PYTHON PROGRAMMING FUNDAMENTALS

Index

- Learning Objectives
- Conditions and Branching
- Loops
- Functions

Learning Objectives

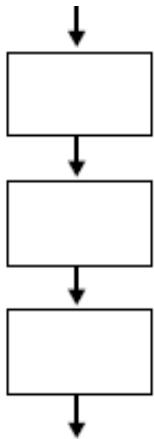

- Know key control structures
- Know how to do small programs
- Know what a function is
- Know how to create simple functions

Control Structure

- Sequencing
- Decision
- Loops

Sequencing

- By default, in a structured language code is interpreted from right to left and top to bottom.

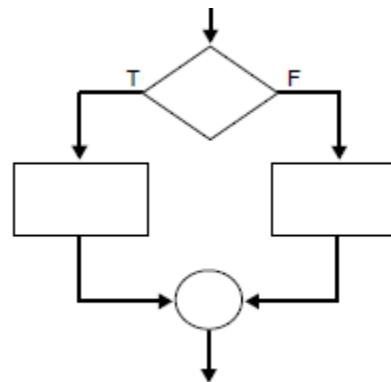

Decision

IF-THEN Statement

```
# A simple decision  
age=?  
if (age >= 18):  
    print("You can vote!")
```

Decision

- IF-THEN statements test for only one action.
- If the condition is true, then an action occurs. If the condition is false, take an alternate action.

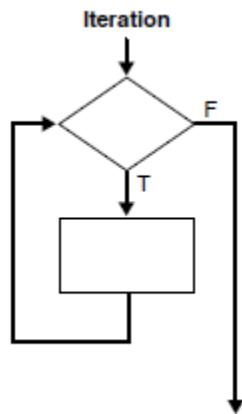

Decision

```
#If-elif-else structure  
if age < 3:  
    ticketPrice= 0  
elif age < 18:  
    ticketPrice = 5  
else: ticketPrice = 10
```

Loops

- A WHILE loop is a process in which a loop is initiated until a condition has been met.
- This structure is useful when performing iterative instructions to satisfy a certain parameter.

Loops

- The loop ends as a result of value entered by user

```
msg = ''  
while msg != 'exit':  
    msg = input("Write a message: ")  
    print(msg)
```

Functions

- Function is a named blocks of code that is used to accomplish a specific purpose.
- Information passed to a function is an argument
- The information received by the function is a parameter

Function

- Simplified Function

```
def greet ():  
    # greeting  
    print ("Hello!")
```

- To call the function, it's called by name:

```
greet ()
```

Function

- For the function to have greater use there is need to pass arguments

```
#argument pass  
def greetUser (name):  
    """ Show a custom message. """  
    print ("Hello, " + name + " !")
```

- Call Example

```
greetUser ("John")
```

Function

- We can have default parameter

```
#argument pass  
def greetUser (name = 'Zézinho'):  
    """ Show a custom message. """  
    print ("Hello," + name + " !")
```

- To call the function

```
greetUser ("John")
```

Function

- Return a value

```
def addValues (x, y):
```

```
"""
```

takes two values and returns the sum.

```
"""
```

```
    return x + y
```

- To call the function

```
sum = addValues (3, 5)
```

```
print (sum)
```

Function

- Sum with default values

```
def addValues (x = 0, y = 0, z = 0):  
    """  
        add multiple values and return the sum.  
    """  
    return x + y + z
```

- Call function

```
sum = addValues (3, 4)  
print (sum)
```
