#### Statistics for Business and Economics 7<sup>th</sup> Edition

#### **Chapter 9**

#### Hypothesis Testing: Single Population

#### **Chapter Goals**

# After completing this chapter, you should be able to:

- Formulate null and alternative hypotheses for applications involving
  - a single population mean from a normal distribution
  - a single population proportion (large samples)
  - the variance of a normal distribution
- Formulate a decision rule for testing a hypothesis
- Know how to use the critical value and p-value approaches to test the null hypothesis (for both mean and proportion problems)
- Know what Type I and Type II errors are
- Assess the power of a test

## What is a Hypothesis?

 A hypothesis is a claim (assumption) about a population parameter:

population mean

9.1

Example: The mean monthly cell phone bill of this city is  $\mu = $42$ 

population proportion

Example: The proportion of adults in this city with cell phones is p = .68

States the assumption (numerical) to be tested

**Example:** The average number of TV sets in U.S. Homes is equal to three  $(H_0 : \mu = 3)$ 

 Is always about a population parameter, not about a sample statistic

- Begin with the assumption that the null hypothesis is true
  - Similar to the notion of innocent until proven guilty
- Refers to the status quo
- Always contains "=", "≤" or "≥" sign
- May or may not be rejected

#### The Alternative Hypothesis, H<sub>1</sub>

Is the opposite of the null hypothesis

- e.g., The average number of TV sets in U.S. homes is not equal to 3 (H<sub>1</sub>: µ ≠ 3)
- Challenges the status quo
- Never contains the "=", "≤" or "≥" sign
- May or may not be supported
- Is generally the hypothesis that the researcher is trying to support

## Level of Significance, $\alpha$

- Defines the unlikely values of the sample statistic if the null hypothesis is true
  - Defines rejection region of the sampling distribution
- Is designated by  $\alpha$ , (level of significance)
  - Typical values are .01, .05, or .10
- Is selected by the researcher at the beginning
- Provides the critical value(s) of the test

#### **Errors in Making Decisions**

#### Type I Error

- Reject a true null hypothesis
- Considered a serious type of error

#### The probability of Type I Error is $\alpha$

- Called level of significance of the test
- Set by researcher in advance

#### Type II Error

Fail to reject a false null hypothesis

The probability of Type II Error is  $\beta$ 

## Type I & II Error Relationship

- Type I and Type II errors can not happen at the same time
  - Type I error can only occur if H<sub>0</sub> is true
  - Type II error can only occur if H<sub>0</sub> is false

If Type I error probability ( 
$$\alpha$$
 ) 1, then  
Type II error probability (  $\beta$  ) 1

- The power of a test is the probability of rejecting a null hypothesis that is false
- i.e., Power =  $P(\text{Reject } H_0 | H_1 \text{ is true})$ 
  - Power of the test increases as the sample size increases

Ch. 9-19

## p-Value Approach to Testing

- p-value: Probability of obtaining a test statistic more extreme ( ≤ or ≥ ) than the observed sample value given H<sub>0</sub> is true
  - Also called observed level of significance
  - Smallest value of α for which H<sub>0</sub> can be rejected

#### p-Value Approach to Testing

(continued)

- Convert sample result (e.g., x̄) to test statistic (e.g., z statistic)
- Obtain the p-value • For an upper tail test:  $p-value = P(z > \frac{\overline{x} - \mu_0}{\sigma/\sqrt{n}}, \text{ given that } H_0 \text{ is true})$   $= P(z > \frac{\overline{x} - \mu_0}{\sigma/\sqrt{n}} \mid \mu = \mu_0)$
- Decision rule: compare the p-value to  $\alpha$

#### Example: Upper-Tail Z Test for Mean (σ Known)

A phone industry manager thinks that customer monthly cell phone bill have increased, and now average over \$52 per month. The company wishes to test this claim. (Assume  $\sigma = 10$  is known)

#### Form hypothesis test:

H <sub>0</sub> : µ ≤ 52	the average is not over \$52 per month
H <sub>1</sub> : μ > 52	the average is greater than \$52 per month (i.e., sufficient evidence exists to support the manager's claim)

(continued)

Obtain sample and compute the test statistic

Suppose a sample is taken with the following results: n = 64,  $\overline{x} = 53.1$  ( $\sigma = 10$  was assumed known)

Using the sample results,

$$z = \frac{\overline{x} - \mu_0}{\frac{\sigma}{\sqrt{n}}} = \frac{53.1 - 52}{\frac{10}{\sqrt{64}}} = 0.88$$

In many cases, the alternative hypothesis focuses on one particular direction

 This is an upper-tail test since the
 alternative hypothesis is focused on the upper tail above the mean of 3

This is a lower-tail test since the
 alternative hypothesis is focused on the lower tail below the mean of 3

Critical value  $\overline{x}_{c}$ 

- State the appropriate null and alternative hypotheses
  - $H_0: \mu = 3$ ,  $H_1: \mu \neq 3$  (This is a two tailed test)
- Specify the desired level of significance
  - Suppose that  $\alpha$  = .05 is chosen for this test
- Choose a sample size
  - Suppose a sample of size n = 100 is selected

## Hypothesis Testing Example

(continued)

- Determine the appropriate technique
  σ is known so this is a z test
- Set up the critical values
  - For  $\alpha$  = .05 the critical z values are ±1.96
- Collect the data and compute the test statistic
  - Suppose the sample results are

n = 100,  $\overline{x}$  = 2.84 ( $\sigma$  = 0.8 is assumed known)

So the test statistic is:

$$z = \frac{\overline{X} - \mu_0}{\frac{\sigma}{\sqrt{n}}} = \frac{2.84 - 3}{\frac{0.8}{\sqrt{100}}} = \frac{-.16}{.08} = -2.0$$

Since z = -2.0 < -1.96, we reject the null hypothesis and conclude that there is sufficient evidence that the mean number of TVs in US homes is not equal to 3

#### t Test of Hypothesis for the Mean (σ Unknown)

(continued)

For a two-tailed test:

Consider the test

$$H_0: \mu = \mu_0$$
$$H_1: \mu \neq \mu_0$$

(Assume the population is normal, and the population variance is unknown)

The decision rule is:

Reject H<sub>0</sub> if 
$$\begin{bmatrix} x - \mu_0 \\ \frac{s}{\sqrt{n}} < -t_{n-1, \alpha/2} \end{bmatrix}$$
 or if  $\begin{bmatrix} x - \mu_0 \\ t = \frac{\overline{x} - \mu_0}{\frac{s}{\sqrt{n}}} > t_{n-1, \alpha/2} \end{bmatrix}$ 

#### Example: Two-Tail Test (σ Unknown)

The average cost of a hotel room in Chicago is said to be \$168 per night. A random sample of 25 hotels resulted in  $\overline{x} = $172.50$  and s = \$15.40. Test at the  $\alpha$  = 0.05 level. (Assume the population distribution is normal)

 $t_{24,.025} = \pm 2.0639$ 

**Do not reject H**<sub>0</sub>: not sufficient evidence that true mean cost is different than \$168

## <sup>9.4</sup> Tests of the Population Proportion

- Involves categorical variables
- Two possible outcomes
  - "Success" (a certain characteristic is present)
  - "Failure" (the characteristic is not present)
- Fraction or proportion of the population in the "success" category is denoted by P
- Assume sample size is large

 When nP(1 – P) > 5, p̂ can be approximated by a normal distribution with mean and standard deviation

$$\square \mu_{\hat{p}} = \mathbf{P}$$

$$\sigma_{\hat{p}} = \sqrt{\frac{P(1-P)}{n}}$$

#### Hypothesis Tests for Proportions

## Example: Z Test for Proportion

A marketing company claims that it receives 8% responses from its mailing. To test this claim, a random sample of 500 were surveyed with 25 responses. Test at the  $\alpha$  = .05 significance level.

#### Critical Values: ± 1.96

#### **Decision:**

Reject  $H_0$  at  $\alpha$  = .05

#### **Conclusion:**

There is sufficient evidence to reject the company's claim of 8% response rate.

- β denotes the probability of Type II Error
- 1 β is defined as the power of the test

# Power = $1 - \beta$ = the probability that a false null hypothesis is rejected

## Type II Error

Assume the population is normal and the population variance is known. Consider the test

$$H_0: \mu = \mu_0$$
  
 $H_1: \mu > \mu_0$ 

The decision rule is:

Reject H<sub>0</sub> if 
$$z = \frac{\overline{x} - \mu_0}{\sigma / \sqrt{n}} > z_{\alpha}$$
 or Reject H<sub>0</sub> if  $\overline{x} = \overline{x}_c > \mu_0 + Z_{\alpha} \sigma / \sqrt{n}$ 

If the null hypothesis is false and the true mean is  $\mu^*$ , then the probability of type II error is

$$\beta = P(\overline{x} < \overline{x}_c \mid \mu = \mu^*) = P\left(z < \frac{\overline{x}_c - \mu^*}{\sigma / \sqrt{n}}\right)$$

#### Type II Error Example Type II error is the probability of failing to reject a false $H_0$ Suppose we fail to reject $H_0$ : $\mu \ge 52$ when in fact the true mean is $\mu^* = 50$ Ω 50 52 Reject Do not reject $H_0: \mu \ge 52$ X<sub>c</sub> $H_0$ : $\mu \ge 52$

Suppose we do not reject H<sub>0</sub>: µ ≥ 52 when in fact the true mean is µ\* = 50

#### Calculating β

• Suppose n = 64 ,  $\sigma$  = 6 , and  $\alpha$  = .05

#### Power of the Test Example

If the true mean is  $\mu^* = 50$ ,

- The probability of Type II Error =  $\beta$  = 0.1539
- The power of the test =  $1 \beta = 1 0.1539 = 0.8461$

	Actual Situation	
Decision	H <sub>0</sub> True	H <sub>0</sub> False
Do Not Reject H <sub>0</sub>	<mark>No error</mark> 1 - α = 0.95	Type II Error β = 0.1539
Reject H <sub>0</sub>	Type I Error α = 0.05	<mark>No Error</mark> 1 - β = 0.8461

(The value of  $\beta$  and the power will be different for each  $\mu^*$ )

Key:

Outcome

(Probability)

Goal: Test hypotheses about the population variance, σ<sup>2</sup>

If the population is normally distributed,

$$\chi^{2}_{n-1} = \frac{(n-1)s^{2}}{\sigma^{2}}$$

has a chi-square distribution with (n - 1) degrees of freedom

#### Hypothesis Tests of one Population Variance

(continued)

The test statistic for hypothesis tests about one population variance is

$$\chi^2_{n-1} = \frac{(n-1)s^2}{\sigma_0^2}$$

Chap 11-57

#### **Chapter Summary**

- Addressed hypothesis testing methodology
- Performed Z Test for the mean (σ known)
- Discussed critical value and p-value approaches to hypothesis testing
- Performed one-tail and two-tail tests
- Performed t test for the mean (σ unknown)
- Performed Z test for the proportion
- Discussed type II error and power of the test
- Performed a hypothesis test for the variance  $(\chi^2)$
