Problem Set 11: Solutions
Risky Debt

1. Present an estimate of the value of debt of a company with the following features:

- Stock Price: 15
- Stock Volatility: 60\%
- Debt Par: 360
- Maturity of Debt: 6 months
- Risk free rate: 3\%
- Bankruptcy cost rate: 0\%

## Market

2. Consider the following application of the debt valuation model of Anderson and Sundaresan (1996), with just two periods (to simplify, consider 2 years). Company LM uses a technology such that the present value of its asset (at $\mathrm{t}=0$ ) is $\mathrm{V} 0=90$. This value evolves annually according to a binomial process with $u=1.25$ and $d=1 / u$. The project generates annual cash flows (ft) proportional to its present value, i.e., $\mathrm{ft}=$ 0.2 Vt . The risk free interest rate is $4 \%$ in both years of analysis (from $t=0$ to $t=1$, and from $t=1$ to $t=2$ ). There is a fixed cost of liquidation of the company, estimated as $K=55$. Suppose that the company issued debt at $t=0$, and that this debt contract requires an annual debt service in $t=1$ and $t=2$ of $C S 1=C S 2=15$. In $t=1$ and $t=2$ the owner/manager chooses the effective debt service to the creditor. If the debt service lies below the contracted amount, the creditor may accept it (and the game continues) or he may liquidate the firm.

Data:
$C S_{1}=C S_{2}=15$
$V_{0}=90$
$R_{f}=4 \%$
$f_{t}=0.2$
Bankruptcy Cost $=K=55$
Tree Parameters:

$$
\begin{aligned}
& D_{t}=1 \\
& u=1.25 \\
& d=0.8 \\
& p=\frac{1.04(1-0.2)-0.8}{1.25-0.8}=0.071
\end{aligned}
$$

Asset Value Tree

| $\mathrm{t}=\mathrm{O}$ | $\mathrm{t}=\mathrm{I}$ | $\mathrm{t}=2$ |
| :---: | :---: | :---: |
| 90 | II2.5 | I 40.625 |
|  | 72.0 | 90 |
|  |  | 57.6 |

Cash Flow Tree

| $\mathrm{t}=\mathrm{O}$ | $\mathrm{t}=\mathrm{I}$ | $\mathrm{t}=2$ |
| :--- | :--- | :--- |
| I 8 | 22.5 | 28.125 |
|  | I4.4 | I8 |
|  |  | II.52 |

(a) What is the debt service that the owner-manager of LM should offer at $\mathrm{t}=1$ and at $\mathrm{t}=2$ ? Explain.

- $\mathrm{T}=2$

The manager will propose to pay:
$S_{2}=\min \left(C S_{2}, \max \left(V_{2}-K, 0\right), f_{2}\right)$
$S_{2}^{++}=\min (15, \max (140.625-55,0), 28.125)=15$
$S_{2}^{+-}=S_{2}^{-+}=\min (15, \max (90-55,0), 18)=15$
$S_{2}^{--}=\min (15, \max (57.6-55,0), 11.52)=2.6$
Note 2: In the final period, the value of debt corresponds to ST, unless there is forced liquidation (which is not the case in this example). Thus:

$$
\begin{aligned}
& B\left(V_{2}^{++}\right)=15 \\
& B\left(V_{2}^{+-}\right)=B\left(V_{2}^{-+}\right)=15 \\
& B\left(V_{2}^{--}\right)=2.6
\end{aligned}
$$

- $\mathrm{t}=\mathrm{I}$

The manager will propose to pay the following debt services:

$$
\begin{aligned}
& S_{1}=\min \left(C S_{1}, \max \left(0, \max \left(V_{1}-K, 0\right)-\frac{p B\left(u V_{1}\right)+(1-p) B\left(d V_{1}\right)}{1+R_{f}}\right), f_{1}\right) \\
& S_{1}^{+}=\min \left(15, \max \left(0, \max (112.5-55,0)-\frac{0.071 * 15+(1-0.187) * 15}{1.04}\right), 22.5\right)=15 \\
& S_{1}^{-}=\min \left(15, \max \left(0, \max (72-55,0)-\frac{0.071 * 15+(1-0.071) * 2.6)}{1.04}\right), 14.4\right)=13.65213675
\end{aligned}
$$

Note: There is strategic default in state -
(b) If I told you that the amount of money borrowed at $\mathrm{t}=0$ was 20 , would that seem credible to you? Explain why.

The present value of this debt (taking into account the debt services chosen in part (a) is inferior to the amount of the loan.

Let's see:

$$
\begin{aligned}
& B\left(V_{1}^{+}\right)=15+\frac{0.071 * 15+(1-0.071) * 15}{1.04}=29.4231 \\
& B\left(V_{1}^{-}\right)=13.65213675+\frac{0.071 * 15+(1-0.071) * 2.6}{1.04}=17 \\
& B\left(V_{0}\right)=\frac{0.071 * 29.4231+(1-0.071) * 17}{1.04}=17.1956
\end{aligned}
$$
