# Stochastic differential equations

• Deterministic ordinary diff. eqs.:

$$f(t,x(t),x'(t),x''(t),\ldots)=0, \quad 0 \leq t \leq T.$$

• 1st order ordinary diff. eq.:

$$\frac{dx(t)}{dt} = \mu(t, x(t))$$

or

$$dx(t) = \mu(t, x(t)) dt$$

Discrete version

$$\Delta x(t) = x(t + \Delta t) - x(t) \approx \mu(t, x(t)) \Delta t$$

• Example:

$$\frac{dx\left(t\right)}{dt}=cx\left(t\right)$$

has solution

$$x(t) = x(0) e^{ct}.$$

#### SDE's

SDE in differential form

$$dX_{t} = \mu(t, X_{t}) dt + \sigma(t, X_{t}) dB_{t},$$

$$X_{0} = X_{0}$$
(1)

- $\mu\left(t,X_{t}\right)$  is the drift coefficient,  $\sigma\left(t,X_{t}\right)$  is the diffusion coefficient.
- SDE in integral form

$$X_t = X_0 + \int_0^t \mu(s, X_s) ds + \int_0^t \sigma(s, X_s) dB_s.$$
 (2)

• "naif"interpretation of SDE:  $\Delta X_t \approx \mu\left(t, X_t\right) \Delta t + \sigma\left(t, X_t\right) \Delta B_t$ . e  $\Delta X_t \approx N\left(\mu\left(t, X_t\right) \Delta t, \left(\sigma\left(t, X_t\right)\right)^2 \Delta t\right)$ .

#### **Definition**

A solution of SDE (1) or (2) is a stochastic process  $\{X_t\}$  which satisfies:

- ①  $\{X_t\}$  is an adapted process (to Bm) and has continuous sample paths.
- $\{X_t\}$  satisfies the SDE (1) or (2)
  - The solutions of SDE's are called diffusions or "diffusion processes".

João Guerra (ISEG)

Models in Finance - Class 5

5 / 24

- The process  $\{X_t, t \geq 0\}$  is said to be a time-homogeneous diffusion process if:
  - 1 it is a Markov process.
  - ② it has continuous sample paths.
  - 3 there exist functions  $\mu\left(x\right)$  and  $\sigma^{2}\left(x\right)>0$  such that as  $\Delta t\rightarrow0^{+}$ ,

$$E\left[X_{t+\Delta t} - X_{t}|X_{t} = x\right] = \Delta t \mu(x) + o\left(\Delta t\right),$$

$$E\left[\left(X_{t+\Delta t} - X_{t}\right)^{2}|X_{t} = x\right] = \Delta t \sigma^{2}(x) + o\left(h\right),$$

$$E\left[\left(X_{t+\Delta t} - X_{t}\right)^{3}|X_{t} = x\right] = o\left(\Delta t\right).$$

- A diffusion is "locally"like Brownian motion with drift, but with a variable drift coefficient  $\mu(x)$  and diffusion coefficient  $\sigma(x)$ .
- Fitting a diffusion model involves estimating the drift function  $\mu(x)$  and the diffusion function  $\sigma(x)$ . Estimating arbitrary drift and diffusion coefficients is virtually impossible unless a very large quantity of data is to hand.
- It is more usual to specify a parametric form of the mean or the variance and to estimate the parameters.

# Solving an SDE by Itô formula

• Exemplo: Standard model for risky asset price (SDE):

$$dS_t = \alpha S_t dt + \sigma S_t dB_t \tag{3}$$

or

$$S_t = S_0 + \alpha \int_0^t S_s ds + \sigma \int_0^t S_s dB_s$$
 (4)

- How to solve this SDE?
- Assume that  $S_t = f(t, B_t)$  with  $f \in C^{1,2}$ . By Itô formula:

$$S_{t} = f(t, B_{t}) = S_{0} + \int_{0}^{t} \left( \frac{\partial f}{\partial t}(s, B_{s}) + \frac{1}{2} \frac{\partial^{2} f}{\partial x^{2}}(s, B_{s}) \right) ds + (5)$$

$$+ \int_{0}^{t} \frac{\partial f}{\partial x}(s, B_{s}) dB_{s}.$$

 Comparing (4) with (5) then (uniqueness of representation as an itô process)

$$\frac{\partial f}{\partial s}(s, B_s) + \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(s, B_s) = \alpha f(s, B_s), \qquad (6)$$

$$\frac{\partial f}{\partial x}(s, B_s) = \sigma f(s, B_s). \tag{7}$$

Differentiating (7) we get

$$\frac{\partial^2 f}{\partial x^2}(s, x) = \sigma \frac{\partial f}{\partial x}(s, x) = \sigma^2 f(s, x)$$

and replacing in (6) we have

$$\left(\alpha - \frac{1}{2}\sigma^2\right)f(s, x) = \frac{\partial f}{\partial s}(s, x)$$

João Guerra (ISEG)

Models in Finance - Class 5

9 / 24

• Separating the variables: f(s, x) = g(s) h(x), we get

$$\frac{\partial f}{\partial s}(s,x) = g'(s) h(x)$$

and

$$g'(s) = \left(\alpha - \frac{1}{2}\sigma^2\right)g(s)$$

wich is a linear ODE, with solution:

$$g\left(s
ight)=g\left(0
ight)\exp\left[\left(lpha-rac{1}{2}\sigma^{2}
ight)s
ight]$$

• Using (7), we get  $h'(x) = \sigma h(x)$  and

$$f(s,x) = f(0,0) \exp \left[\left(\alpha - \frac{1}{2}\sigma^2\right)s + \sigma x\right].$$

Conclusion:

$$S_t = f(t, B_t) = S_0 \exp\left[\left(\alpha - \frac{1}{2}\sigma^2\right)t + \sigma B_t\right]$$
 (8)

which is the geometric Brownian motion. Therefore  $\frac{S_t}{S_0}$  has lognormal distribution with parameters  $(\alpha - \frac{1}{2}\sigma^2) t$  and  $\sigma^2 t$ .

- Remark: Note that the solution of the SDE was obtained by solving a deterministic PDE (partial differential equation).
- Moreover

$$E\left[rac{S_t}{S_0}
ight]=e^{lpha t}$$
, var  $\left[rac{S_t}{S_0}
ight]=e^{2lpha t}\left(e^{\sigma^2 t}-1
ight)$  .

João Guerra (ISEG)

Models in Finance - Class 5

11 / 24

- Let us verify that (8) satisfies SDE (3) or (4).
- Apllying the Itô formula to  $S_t = f(t, B_t)$  with

$$f\left(t,x
ight)=S_{0}\exp\left[\left(lpha-rac{1}{2}\sigma^{2}
ight)t+\sigma x
ight]$$
 ,

we obtain

$$S_t = S_0 + \int_0^t \left[ \left( \alpha - \frac{1}{2} \sigma^2 \right) S_s + \frac{1}{2} \sigma^2 S_s \right] ds + \int_0^t \sigma S_s dB_s$$
  
=  $S_0 + \alpha \int_0^t S_s ds + \sigma \int_0^t S_s dB_s$ 

or:

$$dS_t = \alpha S_t dt + \sigma S_t dB_t.$$

12

João Guerra (ISEG)

• Example: Ornstein-Uhlenbeck process (or Langevin equation):

$$dX_t = \mu X_t dt + \sigma dB_t$$

or

$$X_t = X_0 + \mu \int_0^t X_s ds + \sigma \int_0^t dB_s.$$

Note: in discrete form, we have

$$X_{t+1} = (1 + \mu) X_t + \sigma (B_{t+1} - B_t)$$

or

$$X_{t+1} = \phi X_t + Z_t$$
,

with  $\phi = 1 + \mu$  and  $Z_t \sim N(0, \sigma^2)$ . We have an autoregressive time series of order 1.

João Guerra (ISEG)

Models in Finance - Class 5

13 / 24

- Example: Ornstein-Uhlenbeck process (or Langevin equation):
- Let

$$Y_t = e^{-\mu t} X_t$$

or  $Y_t = f\left(t, X_t
ight)$  with  $f\left(t, x
ight) = e^{-\mu t} x$ . By Itô formula,

$$Y_t = Y_0 + \int_0^t \left( -\mu e^{-\mu s} X_s + \mu e^{-\mu s} X_s + \frac{1}{2} \sigma^2 \times 0 \right) ds$$
  $+ \int_0^t \sigma e^{-\mu s} dB_s.$ 

Therefore,

$$X_t = e^{\mu t} X_0 + e^{\mu t} \int_0^t \sigma e^{-\mu s} dB_s.$$

• If  $X_0 = \text{cte.}$ , this process is called the Ornstein-Uhlenbeck process.

- Example: The Geometric Brownian motion (again)
- Let

$$dS_t = \alpha S_t dt + \sigma S_t dB_t \tag{9}$$

or

$$S_t = S_0 + \alpha \int_0^t S_s ds + \sigma \int_0^t S_s dB_s. \tag{10}$$

Assumption

$$S_t = e^{Z_t}$$
.

or

$$Z_t = \ln(S_t)$$
.

João Guerra (ISEG)

Models in Finance - Class 5

15 / 24

• By the Itô formula, with  $f(x) = \ln(x)$ , we have

$$dZ_t = rac{1}{S_t} dS_t + rac{1}{2} \left(rac{-1}{S_t^2}
ight) \left(dS_t
ight)^2 \ = \left(lpha - rac{1}{2}\sigma^2
ight) dt + \sigma dB_t.$$

ullet That is  $Z_t = Z_0 + \left(lpha - rac{1}{2}\sigma^2
ight)t + \sigma B_t$ and

$$S_t = S_0 \exp \left[ \left( lpha - rac{1}{2} \sigma^2 
ight) t + \sigma B_t 
ight].$$

• In general, the solution of the homogeneous linear SDE

$$dX_{t} = \mu(t) X_{t} dt + \sigma(t) X_{t} dB_{t}$$

is

$$X_{t}=X_{0}\exp\left[\int_{0}^{t}\left(\mu\left(s
ight)-rac{1}{2}\sigma\left(s
ight)^{2}
ight)ds+\int_{0}^{t}\sigma\left(s
ight)dB_{s}
ight].$$

### Ornstein-Uhlenbeck process with mean reversion

$$dX_t = a(m - X_t) dt + \sigma dB_t,$$
  
 $X_0 = x.$ 

 $a, \sigma > 0$  and  $m \in \mathbb{R}$ .

- ullet Solution of the associated ODE  $dx_t = -ax_t dt$  is  $x_t = xe^{-at}$ .
- Consider the variable change  $X_t = Y_t e^{-at}$  or  $Y_t = X_t e^{at}$ .
- By the Itô foemula applied to  $f(t,x) = xe^{at}$ , we have

$$Y_t = x + m \left(e^{at} - 1\right) + \sigma \int_0^t e^{as} dB_s.$$

João Guerra (ISEG)

Models in Finance - Class 5

17 / 24

## Ornstein-Uhlenbeck process with mean reversion

Therefore

$$X_t = m + (x - m) e^{-at} + \sigma e^{-at} \int_0^t e^{as} dB_s.$$

- This is a Gaussian process, since the random part is  $\int_0^t f(s) dB_s$ , where f is deterministic, so it is a Gaussian process.
- Mean:

$$E[X_t] = m + (x - m) e^{-at}$$

### Ornstein-Uhlenbeck process with mean reversion

Covariance: By Itô isometry

$$\begin{aligned} \operatorname{Cov}\left[X_{t}, X_{s}\right] &= \sigma^{2} e^{-a(t+s)} E\left(\int_{0}^{t} e^{ar} dB_{r}\right) \left(\int_{0}^{s} e^{ar} dB_{r}\right) \\ &= \sigma^{2} e^{-a(t+s)} \int_{0}^{t \wedge s} e^{2ar} dr \\ &= \frac{\sigma^{2}}{2a} \left(e^{-a|t-s|} - e^{-a(t+s)}\right). \end{aligned}$$

Note that

$$X_t \sim N \left[ m + (x-m) e^{-at}, rac{\sigma^2}{2a} \left( 1 - e^{-2at} 
ight) 
ight].$$

João Guerra (ISEG)

Models in Finance - Class 5

19 / 24

# Ornstein-Uhlenbeck process with mean reversion

• When  $t \to \infty$ , the distribution of  $X_t$  converges to

$$\nu := N \left[ m, \frac{\sigma^2}{2a} \right].$$

which is the invariant or stationary distribution.

• Note that if  $X_0$  has distribution  $\nu$  then the distribution of  $X_t$  will be  $\nu$  for all t.

# Financial applications of the Ornstein-Uhlenbeck process with mean reversion

Vasicek model for interest rate:

$$dr_t = a(b - r_t) dt + \sigma dB_t$$
,

with  $a, b, \sigma$  real constants.

Solution:

$$r_t = b + (r_0 - b) e^{-at} + \sigma e^{-at} \int_0^t e^{as} dB_s.$$

João Guerra (ISEG)

Models in Finance - Class 5

21 / 24

# Financial applications of the Ornstein-Uhlenbeck process with mean reversion

• Black-Scholes model with stochastic volatility: assume that volatility  $\sigma\left(t\right)=f\left(Y_{t}\right)$  is a function of anOrnstein-Uhlenbeck process with mean reversion :

$$dY_t = a(m - Y_t) dt + \beta dW_t,$$

where  $\{W_t, 0 \le t \le T\}$  is a sBm.

The SDE which models the asset price evolution is

$$dS_t = \alpha S_t dt + f(Y_t) S_t dB_t$$

where  $\{B_t, 0 \le t \le T\}$  is a sBmand the sBm's  $W_t$  and  $B_t$  may be correlated, i.e.,

$$E[B_tW_s] = \rho(s \wedge t)$$
.

### Important theoretical result

Useful theoretical result:

Let  $f:[0,+\infty) \to \mathbb{R}$  be a deterministic function. Then

- ①  $M_t = \exp\left(\int_0^t f(s)dB_s \frac{1}{2}\int_0^t \left(f(s)\right)^2 ds\right)$  is a martingale
- ②  $\int_0^t f(s)dB_s$  has a normal distribution with mean 0 and variance  $\int_0^t (f(s))^2 ds$ .
  - Part 1 is a simple generalization of the fact that  $\exp\left(\lambda B_t \frac{1}{2}\lambda^2 t\right)$  is a martingale.
- Part 2 follows from 1, because martingales have constant mean and  $E\left[M_0\right]=1$  and  $E\left[\exp\left(\lambda\int_0^tf(s)dB_s\right)\right]=\exp\left(\frac{1}{2}\lambda^2\int_0^t\left(f(s)\right)^2ds\right)$ , which is the moment generating function of the  $N\left(0,\int_0^t\left(f(s)\right)^2ds\right)$  distribution.

João Guerra (ISEG)

Models in Finance - Class 5

23 / 24

# AR(1) and mean reverting OU process

Consider the AR(1) process:

$$X_t = \phi X_{t-1} + Z_t,$$

with  $\phi = 1 + \mu$  and  $Z_t \sim \mathcal{N}\left(0, \sigma_e^2\right)$ .

Then

$$egin{aligned} E\left[X_{t}
ight] &= \phi^{n}X_{0},\ Var\left[X_{t}
ight] &= \sigma_{e}^{2}rac{\left(1-lpha^{2n}
ight)}{1-lpha^{2}}. \end{aligned}$$

- These coincide with the values of the mean-reverting Ornstein-Uhlenbeck with m=0 if we put  $\alpha=e^{-a}$  and  $\frac{\sigma_e^2}{1-\alpha^2}=\frac{\sigma^2}{2a}$ .
- The mean-reverting Ornstein-Uhlenbeck process is the continuous equivalent of a AR(1) process such as sBm is the continuous equivalent of a random walk.
