

**CHAPTER 4: PARTIAL EQUILIBRIUM****Exercise 1**

In a perfectly competitive market there are  $J$  firms. Each firm produces output  $q$  according to an identical cost function  $c(q) = k + q^2$ , where  $k > 0$ . Market demand is given by  $Q_d = a - p$ . Assume  $a > 2\sqrt{k}$ .

- Determine the profit-maximizing output of an individual firm.
- Determine the market price and amount produced by all firms in the short-run.
- Assume that the long run cost function is  $c(q) = k + q^2$ ,  $k > 0$ , for  $q > 0$  and  $c(0) = 0$ . Compute the number of firms that are active in this market in the long-run equilibrium (ignoring any integer constraints).

**Exercise 2**

A monopolist faces linear demand  $p = a - bq$  and has cost  $C = cq + F$ , where all parameters are positive,  $a > c$ , and  $(a - c)^2 > 4bF$ .

- Solve for the monopolist's output, price, and profits.
- Calculate the deadweight loss and show that it is positive.

**Exercise 3**

"Consumer surplus is an exact measure of consumer welfare." Under which conditions is this statement true? Explain.

**Exercise 4**

Consider a market structure with  $J$  identical firms with marginal cost  $c \geq 0$ . Let the inverse market demand be given by  $p = a - bQ_d$  for total market output  $Q_d$ .

- Compute total surplus,  $W$ , as a function of  $Q_d$ , when each firm produces the same output  $Q_d/J$ .
- Compute the maximum potential total surplus  $W^*$ .
- In which market structure do we achieve maximum total surplus? Explain briefly.

**Exercise 5**

Consider a consumer whose income is  $y_0$  and consider an inferior (but not Giffen) good  $q$ , whose price falls from  $p_0$  to  $p_1$  (i.e.,  $p_0 > p_1$ ).

- Define compensating variation (CV).
- Graphically represent the CV in the space  $(q, p)$ .
