Stochastic exponential

• Let d = 1 and consider the process $Z = (Z(t), t \ge 0)$ solution of the SDE:

$$dZ(t) = Z(t-) dY(t), (1)$$

where Y is a Lévy-type stochastic integral, of the type:

$$dY(t) = G(t) dt + F(t) dB(t) + \int_{|x| < 1} H(t, x) \widetilde{N}(dt, dx) + \int_{|x| \ge 1} K(t, x) N(dt, dx).$$

 The solution of (1) is the "stochastic exponential" or "Doléans-Dade exponential":

$$Z(t) = \mathcal{E}_{Y}(t) = \exp\left\{Y(t) - \frac{1}{2}[Y_{c}, Y_{c}](t)\right\} \prod_{0 \le s \le t} (1 + \Delta Y(s)) e^{-\Delta Y(s)}.$$
(2)

• We require that (assumption):

$$\inf \{ \Delta Y(t), t > 0 \} > -1 \text{ a.s.}$$
 (3)

Proposition

If Y is a Lévy-type stochastic integral and (3) holds, then each $\mathcal{E}_{Y}(t)$ is a.s. finite.

- Exercise: Prove the previous proposition (see Applebaum)
- Note that (3) also implies that $\mathcal{E}_{Y}(t) > 0$ a.s.
- The stochastic exponential $\mathcal{E}_{Y}(t)$ is the unique solution of SDE (1) which satisfies the initial condition Z(0) = 1 a.s.
- If (3) does not hold then $\mathcal{E}_{Y}(t)$ may take negative values.

2 / 27

Stochastic exponentials

Stochastic exponential

• Alternative form of (2):

$$\mathcal{E}_{Y}(t) = e^{S_{Y}(t)}, \tag{4}$$

where

$$dS_{Y}(t) = F(t) dB(t) + \left(G(t) - \frac{1}{2}F(t)^{2}\right) dt$$

$$+ \int_{|x| \ge 1} \log(1 + K(t, x)) N(dt, dx) + \int_{|x| < 1} \log(1 + H(t, x)) \widetilde{N}(dt, dx)$$

$$+ \int_{|x| < 1} (\log(1 + H(t, x)) - H(t, x)) \nu(dx) dt$$
(5)

Theorem

$$d\mathcal{E}_{Y}(t) = \mathcal{E}_{Y}(t) dY(t)$$

 Exercise: Prove the previous theorem by applying the Itô formula to (5) (see Applebaum).

4/27

Stochastic exponentials

Stochastic exponential

• Example 1: If $Y(t) = \sigma B(t)$, where $\sigma > 0$ and B is a BM, then

$$\mathcal{E}_{Y}(t) = \exp\left\{\sigma B(t) - \frac{1}{2}\sigma^{2}t\right\}.$$

• Example 2: If $Y = (Y(t), t \ge 0)$ is a compound Poisson process: $Y(t) = X_1 + \cdots + X_{N(t)}$ then

$$\mathcal{E}_{Y}\left(t\right)=\prod_{i=1}^{N(t)}\left(1+X_{i}\right)$$

• Example 3: If $Y(t) = \mu t + \sigma B(t) + J(t)$ (jump-diffusion model), where $\sigma > 0$, B is a BM, and $J = (J(t), t \ge 0)$ is a compound Poisson process: $J(t) = X_1 + \cdots + X_{N(t)}$, then

$$\mathcal{E}_{Y}(t) = \exp\left\{\left(\mu - \frac{1}{2}\sigma^{2}\right)t + \sigma B(t)\right\}\prod_{i=1}^{N(t)}(1 + X_{i}).$$

Stochastic exponentials

Stochastic exponential

- Let X be a Lévy process with characteristics (b, σ, ν) and Lévy-Itô decomposition $X(t) = bt + \sigma B(t) + \int_{|x| < 1} x \widetilde{N}(t, dx) + \int_{|x| > 1} x N(t, dx)$.
- When can $\mathcal{E}_X(t)$ be written as $\exp(X_1(t))$ for a certain Lévy process X_1 and vice-versa?
- By (4) and (5) we have $\mathcal{E}_X(t) = e^{S_X(t)}$ with

$$S_{X}(t) = \sigma B(t) + \int_{|x| \ge 1} \log(1+x) N(t, dx) + \int_{|x| < 1} \log(1+x) \widetilde{N}(t, dx) + t \left[b - \frac{1}{2} \sigma^{2} + \int_{|x| < 1} (\log(1+x) - x) \nu(dx) \right].$$
 (6)

Comparing the Lévy-Itô decomposition with (6), we have

Theorem

If X is a Lévy process with each $\mathcal{E}_X(t)$, then $\mathcal{E}_X(t) = \exp(X_1(t))$ where X_1 is a Lévy process with characteristics (b_1, σ_1, ν_1) given by:

$$\begin{split} \nu_1 &= \nu \circ f^{-1}, \quad f(x) = \log \left(1 + x \right). \\ b_1 &= b - \frac{1}{2} \sigma^2 + \int_{\mathbb{R} - \{0\}} \left[\log \left(1 + x \right) \mathbf{1}_{]-1,1[} \left(\log \left(1 + x \right) \right) - x \mathbf{1}_{]-1,1[} \left(x \right) \right] \nu \left(dx \right), \\ \sigma_1 &= \sigma. \end{split}$$

Conversely, there exists a Lévy process X_2 with characteristics (b_2, σ_2, ν_2) such that $\exp(X(t)) = \mathcal{E}_{X_2}(t)$, where

$$u_2 = \nu \circ g^{-1}, \quad g(x) = e^x - 1$$

$$b_2 = b + \frac{1}{2}\sigma^2 + \int_{\mathbb{R} - \{0\}} \left[(e^x - 1) \mathbf{1}_{]-1,1[} (e^x - 1) - x \mathbf{1}_{]-1,1[} (x) \right] \nu(dx),$$

$$\sigma_2 = \sigma.$$

Exponential martingale

Exponential martingales

Lévy-type stochastic integral:

$$dY(t) = G(t) dt + F(t) dB(t) + \int_{|x| < 1} H(t, x) \widetilde{N}(dt, dx)$$
$$+ \int_{|x| \ge 1} K(t, x) N(dt, dx).$$

- When is Y a martingale?
- Assumptions (stronger than necessary to avoid the local martingale concept):

• (M1)
$$\mathbb{E}\left[\int_0^t \int_{|x|\geq 1} |K(s,x)|^2 \nu(dx) ds\right] < \infty$$
 for each $t>0$

• (M2) $\int_0^t \mathbb{E}[|G(s)|] ds < \infty$ for each t > 0.

Exponential martingales

• consequence of (M1) and Cauchy-Schwarz inequality: $\int_0^t \int_{|x|>1} |K(s,x)| \, \nu(dx) \, ds < \infty \text{ a.s.and}$

$$\int_{0}^{t} \int_{|x| \geq 1} K(s, x) N(ds, dx) = \int_{0}^{t} \int_{|x| \geq 1} K(s, x) \widetilde{N}(ds, dx) + \int_{0}^{t} \int_{|x| \geq 1} K(s, x) \nu(ds, dx)$$

and the compensated integral is a martingale.

Theorem

With assumptions (M1) and (M2), Y is a martingale if and only if

$$G(t) + \int_{|x|>1} K(t,x) \nu(dx) = 0$$
 (a.s.) for a.a. $t \ge 0$.

(see the proof in Applebaum)

Exponential martingale

Exponential martingales

- Let us consider the process $e^{Y} = (e^{Y(t)}, t \ge 0)$.
- By Itô's formula, we have that

$$e^{Y(t)} = 1 + \int_{0}^{t} e^{Y(s-)} F(s) dB(s) + \int_{0}^{t} \int_{|x|<1} e^{Y(s-)} \left(e^{H(s,x)} - 1 \right) \widetilde{N}(ds, dx)$$

$$+ \int_{0}^{t} \int_{|x|\geq 1} e^{Y(s-)} \left(e^{K(s,x)} - 1 \right) \widetilde{N}(ds, dx)$$

$$+ \int_{0}^{t} e^{Y(s-)} \left(G(s) + \frac{1}{2} F(s)^{2} + \int_{|x|<1} \left(e^{H(s,x)} - 1 - H(s,x) \right) \nu(dx) + \int_{|x|\geq 1} \left(e^{K(s,x)} - 1 \right) \nu(dx) ds$$

$$(7)$$

Exponential martingales

Theorem

e^Y is a martingale if and only if

$$G(s) + \frac{1}{2}F(s)^{2} + \int_{|x|<1} \left(e^{H(s,x)} - 1 - H(s,x)\right)\nu(dx) + \int_{|x|>1} \left(e^{K(s,x)} - 1\right)\nu(dx) = 0$$
(8)

a.s. and for a.a. $s \ge 0$.

Therefore, if e^Y is a martingale then

$$\begin{split} e^{Y(t)} &= 1 + \int_0^t e^{Y(s-)} F(s) \, dB(s) + \int_0^t \int_{|x| < 1} e^{Y(s-)} \left(e^{H(s,x)} - 1 \right) \widetilde{N} \, (ds, dx) \\ &+ \int_0^t \int_{|x| \ge 1} e^{Y(s-)} \left(e^{K(s,x)} - 1 \right) \widetilde{N} \, (ds, dx) \, . \end{split}$$

João Guerra (CEMAPRE and ISEG, UTL)

Stochastic exponential, exponential martingales and co

November 10, 2014

12 / 27

Exponential martingale

Exponential martingales

- If e^Y is a martingale then $\mathbb{E}\left[e^{Y(t)}\right] = 1$ for all $t \ge 0$ and e^Y is called an exponential martingale.
- if Y is an Itô process: $Y(t) = \int_0^t G(s) ds + \int_0^t F(s) dB(s)$ then (8) is $G(t) = -\frac{1}{2}F(t)^2$ and

$$e^{Y(t)} = \exp\left(\int_0^t F(s) dB(s) - \frac{1}{2} \int_0^t F(s)^2 ds\right).$$

Change of Measure - Girsanov's Theorem

- Let P and Q be two different probability measures. Q_t and P_t are the measures restricted to (Ω, \mathcal{F}_t) .
- Let e^{Y} be an exponential martingale and define Q_t by

$$\frac{dQ_t}{dP_t} = e^{Y(t)}.$$

• Fix an interval [0, T] and define $P = P_T$ and $Q = Q_T$.

Lemma

 $M=(M(t), 0 \leq t \leq T)$ is a Q-martingale if and only if $Me^Y=(M(t)e^{Y(t)}, 0 \leq t \leq T)$ is a P-martingale.

João Guerra (CEMAPRE and ISEG, UTL)

Stochastic exponential, exponential martingales and co

November 10, 2014

14 / 27

Change of Measure - Girsanov's Theorem

Change of Measure - Girsanov's Theorem

- Let Y be an Itô process (or Brownian integral) and $e^{Y(t)} = \exp\left(\int_0^t F(s) dB(s) \frac{1}{2} \int_0^t F(s)^2 ds\right)$.
- Define a new process

$$B_{Q}(t) = B(t) - \int_{0}^{t} F(s) ds.$$

Theorem

(Girsanov): B_Q is a Q-Brownian motion.

• Generalization of Girsanov: Let M be a martingale of the form $M(t) = \int_0^t \int_A L(x, s) \widetilde{N}(ds, dx)$, with L predictable, $L \in \mathcal{P}_2$. Then

$$N(t) = M(t) - \int_0^t \int_A L(s, x) \left(e^{H(s, x)} - 1 \right) \nu(dx) ds$$

is a Q-martingale.

15 / 27

Option pricing

- Stock price: $S = (S(t), t \ge 0)$.
- Contingent claims with maturity date T: Z is a non-negative \mathcal{F}_T measurable r.v. representing the payoff of the option.
- European call option: $Z = \max \{S(T) K, 0\}$
- American call option: $Z = \sup_{0 \le \tau \le T} [\max \{S(\tau) K, 0\}]$
- Asian option: $Z = \max \left\{ \frac{1}{T} \int_0^T (S(t) K) dt, 0 \right\}$
- We assume that the interest rate r is constant.
- Discounted stock price process: $\widetilde{S} = (\widetilde{S}(t), t \ge 0)$ with $\widetilde{S}(t) = e^{-rt}S(t)$.
- Portfolio: $(\alpha(t), \beta(t)), \alpha(t)$ is the number of shares and $\beta(t)$ the number of riskless assets (bonds).
- Portfolio value: $V(t) = \alpha(t) S(t) + \beta(t) A(t)$
- A portfolio is said to be replicating if V(T) = Z.

João Guerra (CEMAPRE and ISEG, UTL)

Stochastic exponential, exponential martingales and co

November 10, 2014

16 / 27

Lévy Processes in Option Pricing

Option pricing

- Self-financing portfolio: $dV(t) = \alpha(t) dS(t) + r\beta(t) A(t) dt$.
- A market is said to be complete if every contingent claim can be replicated by a self-financing portfolio.
- An arbitrage opportunity exists if the market allows risk-free profit. The market is arbitrage free if there exists no self-financing strategy for which V(0) = 0, $V(T) \ge 0$ and P(V(T) > 0) > 0.

Theorem

(Fundamental Theorem of Asset Pricing 1 in discrete time) If the market is free of arbitrage opportunities, then there exists a probability measure \mathbb{Q} , which is equivalent to P, with respect to which the discounted process \widetilde{S} is a martingale.

 A similar result holds in the continuous case but we need to make more technical assumptions - instead of absence of arbitrage we need the stronger NFLVR hypothesis ("no free lunch with vanishing risk").

17 / 27

Option pricing

Theorem

Fundamental Theorem of Asset Pricing 2) An arbitrage-free market is complete if and only if there exists a unique probability measure Q, which is equivalent to P, with respect to which the discounted process \widetilde{S} is a martingale.

- Such a Q is called a martingale measure or risk-neutral measure.
- If Q exists, but is not unique, then the market is said to be incomplete.
- In a complete market, it turns out that we have

$$V(t) = e^{-r(T-t)} \mathbb{E}_{Q} [Z|\mathcal{F}_{t}]$$

and this is the arbitrage-free price of the claim Z at time t.

18 / 27

Lévy Processes in Option Pricing

Stock price as a Lévy process

Return:

$$\frac{\delta S(t)}{S(t)} = \sigma \delta X(t) + \mu \delta t,$$

where $X = (X(t), t \ge 0)$ is a Lévy process and $\sigma > 0, \mu$ are parameters called the volatility and stock drift.

Itô calculus SDE:

$$dS(t) = \sigma S(t-) dX(t) + \mu S(t-) dt$$

= $S(t-) dZ(t)$,

where
$$Z(t) = \sigma X(t) + \mu t$$
.

• Then $S(t) = \mathcal{E}_{Z(t)}$ is the stochastic exponential of Z.

Stock price as a Lévy process

 When X is a standard Brownian motion B, we obtain the geometric Brownian motion

$$S(t) = \exp\left(\sigma B(t) + \left(\mu - \frac{1}{2}\sigma^2\right)t\right)$$

- idea: Let X be a Lévy process. In order for stock prices to be non-negative, (3) yields $\Delta X(t) > -\sigma^{-1}$ (a.s.) for each t > 0. Denote $c = -\sigma^{-1}$.
- We impose $\int_{(c,-1]\cup[1,+\infty)} x^2 \nu(dx) < \infty$. This means that each X(t) has first and second moments (reasonable for stock returns).
- By the Lévy-Itô decomposition,

$$X(t) = mt + kB(t) + \int_{c}^{\infty} x\widetilde{N}(t, dx),$$

where $k \ge 0$ and $m = b + \int_{(c,-1] \cup [1,+\infty)} x \nu(dx)$ (in terms of the earlier parameters).

João Guerra (CEMAPRE and ISEG, UTL)

Stochastic exponential, exponential martingales and co

November 10, 2014

20 / 27

Lévy Processes in Option Pricing

Stock price as a Lévy process

• Representing S(t) as the stochastic exponential $\mathcal{E}_{Z(t)}$, we obtain from (5) that

$$d(\log(S(t))) = k\sigma dB(t) + \left(m\sigma + \mu - \frac{1}{2}k^2\sigma^2\right)dt$$
$$+ \int_{c}^{\infty} \log(1 + \sigma x)\widetilde{N}(dt, dx) + \int_{c}^{\infty} (\log(1 + \sigma x) - \sigma x)\nu(dx) dt$$

• There are a number of explicit mathematically tractable and realistic models: variance-gamma, normal inverse Gaussian, hyperbolic, etc.

Change of measure

- we seek to find measures Q, which are equivalent to P, with respect to which the discounted stock process \widetilde{S} is a martingale.
- Let Y be a Lévy-type stochastic integral of the form:

$$dY(t) = G(t) dt + F(t) dB(t) + \int_{\mathbb{R}-\{0\}} H(t,x) \widetilde{N}(dt,dx).$$

- Consider that e^Y is an exponential martingale (therefore, G is determined by F and H).
- Define Q by $\frac{dQ}{dP} = e^{Y(T)}$. By Girsanov theorem and its generalization:

$$B_{Q}(t) = B(t) - \int_{0}^{t} F(s) ds$$
 is a Q-BM $\widetilde{N}_{Q}(t,A) = \widetilde{N}(t,A) - \nu_{Q}(t,A)$ is a Q-martingale $\nu_{Q}(t,A) := \int_{0}^{t} \int_{A} \left(e^{H(s,x)} - 1\right) \nu(dx) ds.$

João Guerra (CEMAPRE and ISEG, UTL)

Stochastic exponential, exponential martingales and co

November 10, 2014

22 / 27

Lévy Processes in Option Pricing

Change of measure

• $\widetilde{S}(t) = e^{-rt}S(t)$ can be written in terms of these processes by:

$$d\left(\log\left(\widetilde{S}\left(t\right)\right)\right) = k\sigma dB_{Q}(t) + \left(m\sigma + \mu - r - \frac{1}{2}k^{2}\sigma^{2} + k\sigma F\left(t\right)\right)$$

$$+\sigma \int_{\mathbb{R}-\{0\}} x\left(e^{H(t,x)} - 1\right)\nu\left(dx\right)dt + \int_{c}^{\infty} \log\left(1 + \sigma x\right)\widetilde{N}_{Q}\left(dt, dx\right)$$

$$+\int_{c}^{\infty} \left(\log\left(1 + \sigma x\right) - \sigma x\right)\nu_{Q}\left(dt, dx\right).$$

• Put $\widetilde{S}(t) = \widetilde{S}_1(t) \widetilde{S}_2(t)$, where

$$d\left(\log\left(\widetilde{S}_{1}(t)\right)\right) = k\sigma dB_{Q}(t) - \frac{1}{2}k^{2}\sigma^{2}dt + \int_{c}^{\infty}\log\left(1 + \sigma x\right)\widetilde{N}_{Q}(dt, dx) + \int_{c}^{\infty}\left(\log\left(1 + \sigma x\right) - \sigma x\right)\nu_{Q}(dt, dx).$$

Change of measure

and

$$d\left(\log\left(\widetilde{S}_{2}\left(t\right)\right)\right) = \left(m\sigma + \mu - r + k\sigma F\left(t\right) + \sigma \int_{\mathbb{R}-\left\{0\right\}} x\left(e^{H\left(t,x\right)} - 1\right)\nu\left(dx\right)\right)dt.$$

• Apllying Itô's formula to \widetilde{S}_1 we obtain:

$$d\widetilde{S}_{1}(t) = k\sigma\widetilde{S}_{1}(t-)dB_{Q}(t) + \int_{c}^{\infty} \sigma\widetilde{S}_{1}(t-)x\widetilde{N}_{Q}(dt,dx).$$

and \widetilde{S}_1 is a Q-martingale.

• Therefore S is a Q-martingale if and only if

$$m\sigma + \mu - r + k\sigma F(t) + \sigma \int_{\mathbb{R} - \{0\}} x \left(e^{H(t,x)} - 1\right) \nu(dx) = 0$$
 a.s. (9)

João Guerra (CEMAPRE and ISEG, UTL)

Stochastic exponential, exponential martingales and co

November 10, 2014

24 / 27

Lévy Processes in Option Pricing

Change of measure

- Equation (9) clearly has an infinite number of possible solution pairs (F, H).
- There are an infinite number of possible measures Q with respect to which S is a martingale. So the general Lévy process model gives rise to incomplete markets.
- Example the Brownian motion case: $\nu = 0$ and $k \neq 0$. Then there is a unique solution

$$F(t) = \frac{r - \mu - m\sigma}{k\sigma}$$
 a.s.

and the market is complete (Black-Scholes model).

Change of measure

• Example - the Poisson Process case:take k=0 and $\nu(x)=\lambda\delta_1(x)$. Then $X(t)=mt+\int_c^\infty x\widetilde{N}(t,dx)$, where the jump part is the standard Poisson process N(t). Writing H(t,1)=H(t), we have from (9) that

$$m\sigma + \mu - r + \sigma\lambda\left(e^{H(t)} - 1\right) = 0$$
 a.s.

and

$$H(t) = \log \left(\frac{r - \mu + (\lambda - m) \sigma}{\lambda \sigma} \right).$$

In this case, the market is also complete and we obtain a martingale measure if $r - \mu + (\lambda - m) \sigma > 0$.

 In most part of the other cases (with other Lévy processes), the market is incomplete.
