Basic Regression Analysis with Time Series Data

Chapter 8 (Ch. 10 of the textbook)

Wooldridge: Introductory Econometrics: A Modern Approach, 5e

The nature of time series data

- Temporal ordering of observations; may not be arbitrarily reordered
- Typical features: serial correlation/nonindependence of observations
- How should we think about the randomness in time series data?
 - The outcome of economic variables (e.g. GNP, Dow Jones) is uncertain; they should therefore be modeled as random variables
 - Time series are sequences of r.v. (= stochastic processes)
 - Randomness does not come from sampling from a population
 - "Sample" = the one realized path of the time series out of the many possible paths the stochastic process could have taken

1

Example: US inflation and unemployment rates 1948-2003

Year	Inflation	Unemployment
1948	8.1	3.8
1949	-1.2	5.9
1950	1.3	5.3
1951	7.9	3.3
·	÷	
1998	1.6	4.5
1999	2.2	4.2
2000	3.4	4.0
2001	2.8	4.7
2002	1.6	5.8
2003	2.3	6.0

 Here, there are only two time series. There may be many more variables whose paths over time are observed simultaneously.

<u>Time series analysis focuses on modeling the</u> <u>dependency of a variable on its own past, and</u> <u>on the present and past values of other variables.</u>

- Examples of time series regression models
- Static models
 - In static time series models, the current value of one variable is modeled as the result of the current values of explanatory variables
- Examples for static models

There is a contemporaneous relationship between unemployment and inflation (= Phillips-Curve).

$$inf_{t} = \beta_0 + \beta_1 unem_{t} + u_t$$

$$mrdrte_{f} = \beta_0 + \beta_1 convrte_{f} + \beta_2 unem_{f} + \beta_3 yngmle_{f} + u_t$$

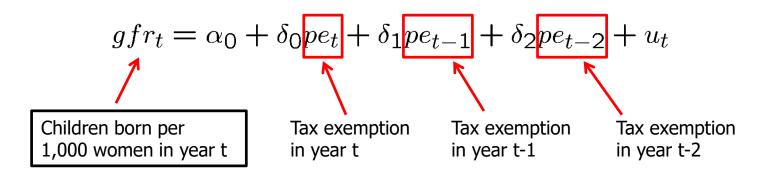

The <u>current</u> murderrate is determined by the <u>current</u> conviction rate, unemployment rate, and fraction of young males in the population.

Finite distributed lag models

 In finite distributed lag models, the explanatory variables are allowed to influence the dependent variable with a time lag

Example for a finite distributed lag model

 The fertility rate may depend on the tax value of a child, but for biological and behavioral reasons, the effect may have a lag

4

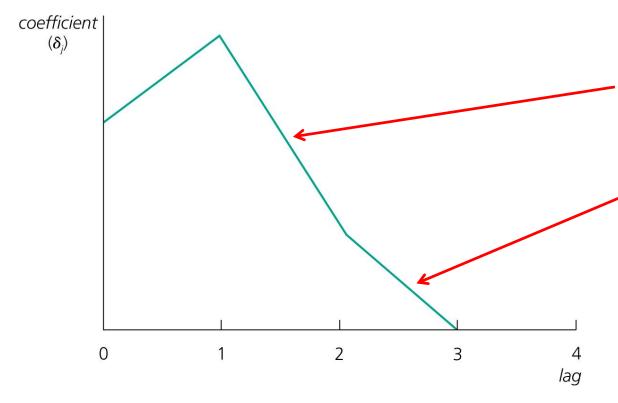

Interpretation of the effects in finite distributed lag models

 $y_t = \alpha_0 + \delta_0 z_t + \delta_1 z_{t-1} + \dots + \delta_q z_{t-q} + u_t$

Effect of a past shock on the current value of the dep. variable

Graphical illustration of lagged effects

For example, the effect is biggest after a lag of one period. After that, the effect vanishes (if the initial shock was transitory).

The long run effect of a permanent shock is the cumulated effect of all relevant lagged effects. It does not vanish (if the initial shock is a permanent one).

6

- Finite sample properties of OLS under classical assumptions
- Assumption TS.1 (Linear in parameters)

$$y_t = \beta_0 + \beta_1 x_{t1} + \beta_2 x_{t2} + \ldots + \beta_k x_{tk} + u_t$$

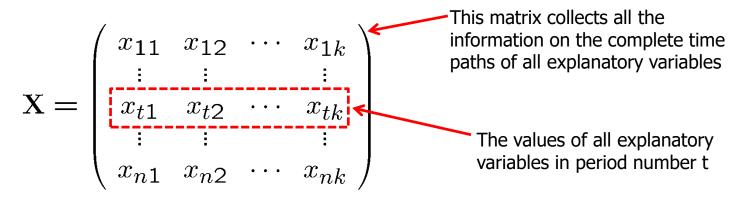

The time series involved obey a linear relationship. The stochastic processes y_t , x_{t1} ,..., x_{tk} are observed, the error process u_t is unobserved. The definition of the explanatory variables is general, e.g. they may be lags or functions of other explanatory variables.

Assumption TS.2 (No perfect collinearity)

"In the sample (and therefore in the underlying time series process), no independent variable is constant nor a perfect linear combination of the others."

7

Notation

Assumption TS.3 (Zero conditional mean)

 $E(u_t|\mathbf{X}) = 0$ The mean value of the unobserved factors is unrelated to the values of the explanatory variables <u>in all periods</u>

8

Discussion of assumption TS.3

<u>Contemp. Exogeneity:</u> $E(u_t | \mathbf{x}_t) = 0^{\bigstar}$

Strict exogeneity: $E(u_t|\mathbf{X}) = 0$

The mean of the error term is unrelated to the explanatory variables <u>of the same period</u>

The mean of the error term is unrelated to the values of the explanatory variables <u>of all periods</u>

9

Sequential exog.: $E(u_t | \mathbf{x}_t, \mathbf{x}_{t-1}, \dots) = E(u_t) = 0$

Strict exogeneity is stronger than contemporaneous exogeneity

- TS.3 rules out <u>feedback</u> from the dep. variable on future values of the explanatory variables; this is often questionable esp. if explanatory variables "adjust" to past changes in the dependent variable
- If the error term is related to past values of the explanatory variables, one should include these values as contemporaneous regressors

- Theorem 10.1 (Unbiasedness of OLS)
- $TS.1-TS.3 \Rightarrow E(\hat{\beta}_j) = \beta_j, \quad j = 0, 1, \dots, k$

Assumption TS.4 (Homoscedasticity)

 $Var(u_t|\mathbf{X}) = Var(u_t) = \sigma^2$ The volatility of the errors must not be related to the explanatory variables in any of the periods

- A sufficient condition is that the volatility of the error is independent of the explanatory variables and that it is constant over time
- In the time series context, homoscedasticity may also be easily violated,
 e.g. if the volatility of the dep. variable depends on regime changes
 10

Assumption TS.5 (No serial correlation)

 $Corr(u_t, u_s | \mathbf{X}) = 0, \ t \neq s \checkmark$

Conditional on the explanatory variables, the unobserved factors must not be correlated over time

Discussion of assumption TS.5

- Why was such an assumption not made in the cross-sectional case?
- The assumption may easily be violated if, conditional on knowing the values of the indep. variables, omitted factors are correlated over time
- The assumption may also serve as substitute for the random sampling assumption if sampling a cross-section is not done completely randomly
- In this case, given the values of the explanatory variables, errors have to be uncorrelated across cross-sectional units (e.g. states)
 11

Theorem 10.2 (OLS sampling variances)

The conditioning on the values of the explanatory variables is not easy to understand. It effectively means that, in a finite sample, one ignores the sampling variability coming from the randomness of the regressors. This kind of sampling variability will normally not be large (because of the sums).

Theorem 10.3 (Unbiased estimation of the error variance)

$$TS.1 - TS.5 \Rightarrow E(\hat{\sigma}^2) = \sigma^2$$

Theorem 10.4 (Gauss-Markov Theorem)

- Under assumptions TS.1 TS.5, the OLS estimators have the minimal variance of all linear unbiased estimators of the regression coefficients
- This holds conditional as well as unconditional on the regressors
- Assumption TS.6 (Normality)
 This assumption implies TS.3 TS.5

 $u_t \sim N(0, \sigma^2)$ independently of **X**

- Theorem 10.5 (Normal sampling distributions)
 - Under assumptions TS.1 TS.6, the OLS estimators have the usual normal distribution (conditional on X). The usual F- and t-tests are valid.
 13

Example: Static Phillips curve

$$\widehat{inf}_t = 1.42 + .468 unem_t^{\prime}$$

(1.72) (.289)

$$n = 49, R^2 = .053, \bar{R}^2 = .033$$

Discussion of CLM assumptions

TS.1:
$$inf_t = \beta_0 + \beta_1 unem_t + u_t$$

Contrary to theory, the estimated Phillips Curve does not suggest a tradeoff between inflation and unemployment

> The error term contains factors such as monetary shocks, income/demand shocks, oil price shocks, supply shocks, or exchange rate shocks

<u>TS.2:</u> A linear relationship might be restrictive, but it should be a good approximation. Perfect collinearity is not a problem as long as unemployment varies over time.

Discussion of CLM assumptions (cont.)

TS.3:
$$E(u_t | unem_1, \dots, unem_n) = 0$$
 Easily violated

$$unem_{t-1} \uparrow \rightarrow u_t \downarrow \longleftarrow$$

For example, past unemployment shocks may lead to future demand shocks which may dampen inflation

 $u_{t-1} \uparrow \rightarrow unem_t \uparrow$ For example, an oil price shock means more inflation and may lead to future increases in unemployment

TS.4:
$$Var(u_t | unem_1, \dots, unem_n) = \sigma^2 \checkmark$$

Assumption is violated if monetary policy is more "nervous" in times of high unemployment

TS.5:
$$Corr(u_t, u_s | unem_1, \dots, unem_n) = 0$$
 Assumption is violated if ex-

<u>TS.6</u>: $u_t \sim N(0, \sigma^2)$ Questionable

Assumption is violated if exchange rate influences persist over time (they cannot be explained by unemployment)

Example: Effects of inflation and deficits on interest rates

Interest rate on 3-months T-bill Government deficit as percentage of GDP

$$\widehat{i3}_t = 1.73 + .606 \ inf_t + .513 \ def_t$$

(0.43) (.082) (.118)

$$n = 56, R^2 = .602, \bar{R}^2 = .587$$

The error term represents other factors that determine interest rates in general, e.g. business cycle effects

<u>TS.1:</u> $i3_t = \beta_0 + \beta_1 inf_t + \beta_2 def_t + u_t$

Discussion of CLM assumptions

<u>TS.2:</u> A linear relationship might be restrictive, but it should be a good approximation. Perfect collinearity will seldomly be a problem in practice.

Discussion of CLM assumptions (cont.)

<u>TS.3:</u> $E(u_t | inf_1, \dots, inf_n, def_1, \dots, def_n) = 0$ \leftarrow Easily violated

$$def_{t-1} \uparrow \rightarrow u_t \uparrow \longleftarrow$$

For example, past deficit spending may boost economic activity, which in turn may lead to general interest rate rises

 $u_{t-1} \uparrow \rightarrow inf_t \uparrow \longleftarrow$

For example, unobserved demand shocks may increase interest rates and lead to higher inflation in future periods

TS.4:
$$Var(u_t|inf_1,\ldots,def_n) = \sigma^2 \checkmark$$

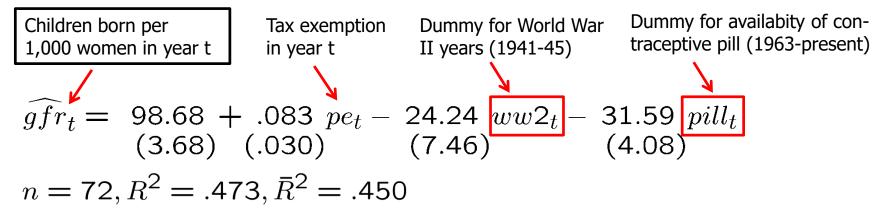

TS.5:
$$Corr(u_t, u_s | inf_1, \dots, def_n) = 0 \leftarrow$$

TS.6:
$$u_t \sim N(0, \sigma^2)$$
 Questionable

 Assumption is violated if higher deficits lead to more uncertainty about state finances and possibly more abrupt rate changes

Assumption is violated if business cylce effects persist across years (and they cannot be completely accounted for by inflation and the evolution of deficits)

- Functional Form and Dummy Variables:
- Example 1:

- Interpretation
 - During World War II, the fertility rate was temporarily lower
 - It has been permanently lower since the introduction of the pill in 1963

Example 2:

- Krupp and Pollard (1996) analyzed the effects of antidumping filings by U.S. chemical industries on imports of various chemicals.
- We focus here on <u>barium chloride</u>, a cleaning agent used in various chemical processes and in gasoline production.
- Important events:
 - In the early 1980s, U.S. barium chloride producers believed that China was offering its U.S. imports at an unfairly low price (an action known as dumping), and the barium chloride industry <u>filed a complaint</u> with the U.S. International Trade Commission (ITC) <u>in October 1983</u>.
 - The ITC ruled in favor of the U.S. barium chloride industry in October 1984.

Questions

- Were imports unusually high in the period immediately preceding the initial filing?
- Did imports change noticeably after an antidumping filing?
- What was the reduction in imports after a decision in favor of the U.S. industry?
- Need of dummy variables (following Krupp and Pollard)
 - **befile6:** is equal to 1 during the six months before filing
 - **affile6:** is equal to 1 during the six months after filing
 - **afdec6:** is equal to 1 the six months after the positive decision

The model:Using monthly data from February 1978 through December 1988

$$\begin{split} \hat{\log}(chnimp) &= -17.80 + 13.12 \log(chempi) + 0.196 \log(gas) \\ &(21.05) \ (0.48) \\ &+ 0.983 \log(rtwex) + 0.060 be filed 6 - 0.032 affile 6 - 0.565 af dec 6 \\ &(0.400) \\ &(0.261) \\ &(0.264) \\ &(0.286) \\ n &= 131, R^2 = 305 \end{split}$$

chnimp – the volume of imports of barium chloride from China,

chempi – the index of chemical production (to control for overall demand for barium chloride), defined to be 100 in June 1977

gas - the volume of gasoline production, (another demand variable)

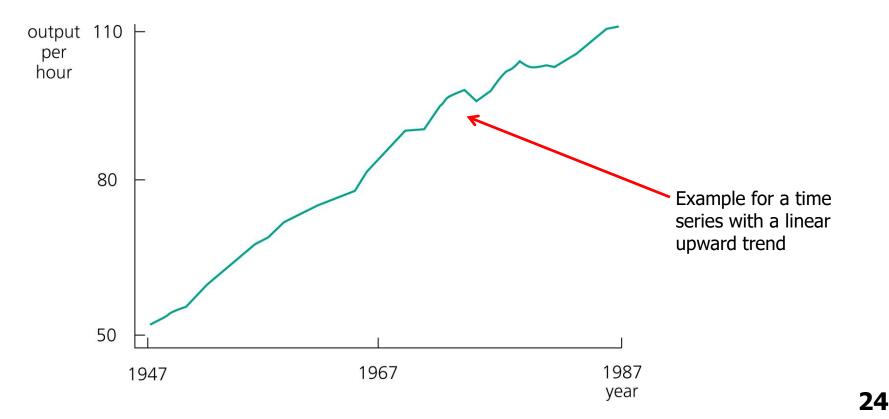

rtwex - the exchange rate index which measures the strength of the dollar against several other currencies. **21**

Conclusions

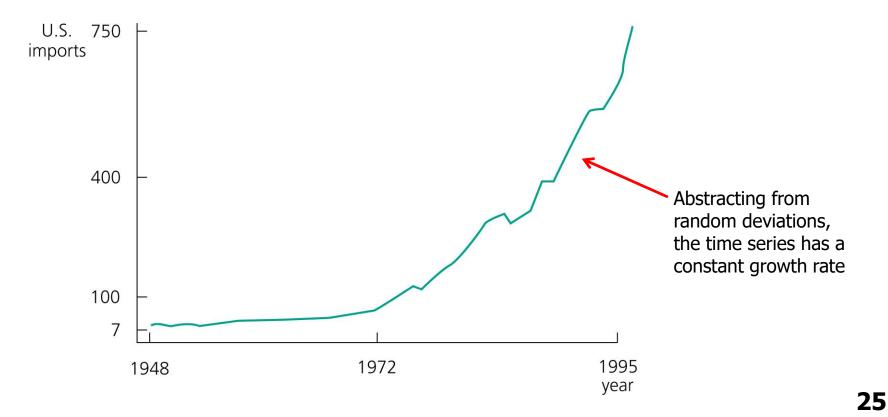

- befile6 is statistically insignificant, so there is no evidence that Chinese imports were unusually high during the six months before the suit was filed.
- although the estimate on affile6 is negative, the coefficient is small (indicating about a 3.2% fall in Chinese imports), and it is statistically very insignificant.
- The coefficient on afdec6 shows a substantial fall in Chinese imports of barium chloride after the decision in favor of the U.S. industry. The exact percentage change is -43.2%. The coefficient is statistically significant at the 5% level against a twosided alternative.

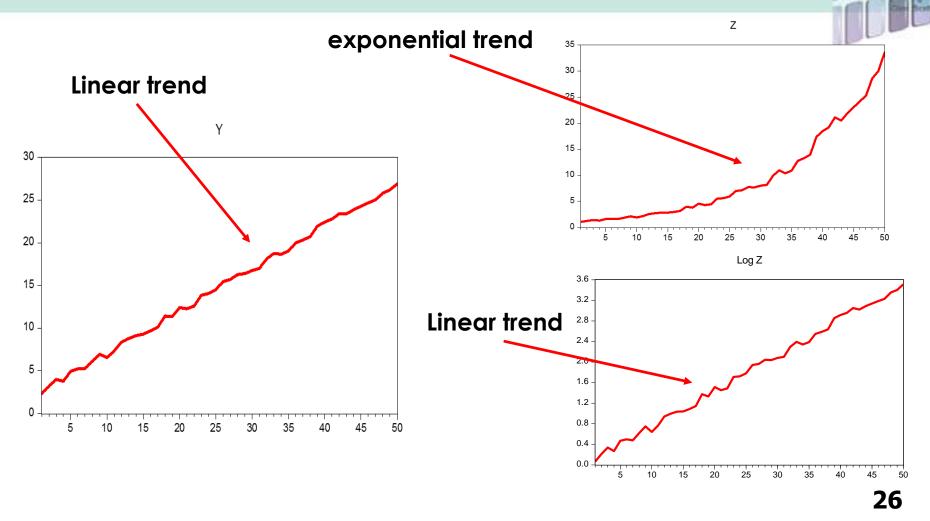

- Conclusions: coefficient signs on the control variables are what we expect:
 - an increase in overall chemical production increases the demand for the cleaning agent.
 - Gasoline production does not affect Chinese imports significantly.
 - The coefficient on log(rtwex) shows that an increase in the value of the dollar relative to other currencies increases the demand for Chinese imports, as is predicted by economic theory

Time series with trends

Example for a time series with an exponential trend

Modelling a linear time trend

$$y_t = \alpha_0 + \alpha_1 t + e_t \quad \Leftrightarrow \quad E(\Delta y_t) = E(y_t - y_{t-1}) = \alpha_1$$

$$\partial y_t / \partial t = \alpha_1 \longleftarrow$$

Abstracting from random deviations, the dependent variable increases by a constant amount per time unit

$$E(y_t) = \alpha_0 + \alpha_1 t \longleftarrow$$

Alternatively, the expected value of the dependent variable is a linear function of time

Example

$$\hat{y}_t = 8633.33 + 294.84t$$

disposable income 1992 billions of \$ Annual data In average the disposable income increases by 294.84 billions of dollars per year

Modelling an exponential time trend

$$\log(y_t) = \alpha_0 + \alpha_1 t + e_t$$

$$\Leftrightarrow \quad E(\Delta \log(y_t)) = \alpha_1$$

 $(\partial y_t/y_t)/\partial t = \alpha_1 \longleftarrow$

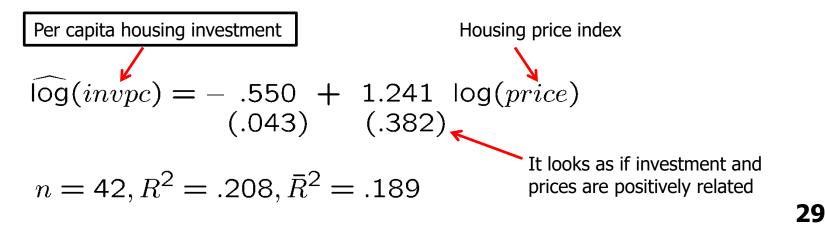

Abstracting from random deviations, the dependent variable increases by <u>a constant percentage per time unit</u>

Example

The disposable income increases in average by 2.2% per vear

 $log(y_t) = 9.11 + 0.022t$

- Using trending variables in regression analysis
 - If trending variables are regressed on each other, a **spurious** relationship may arise if the variables are driven by a common trend
 - In this case, it is important to include a trend in the regression
- **Example: Housing investment and prices**

Example: Housing investment and prices (cont.)

$$\widehat{\log(invpc)} = -.913 + .381 \log(price) + .0098 t$$
(.136) (.679)
(.0035)

$$n = 42, R^2 = .341, \bar{R}^2 = .307$$

There is no significant relationship between price and investment anymore

When should a trend be included?

- If the dependent variable displays an obvious trending behaviour
- If both the dependent and some independent variables have trends
- If only some of the independent variables have trends; their effect on the dep. var. may only be visible after a trend has been substracted

A Detrending interpretation of regressions with a time trend

- It turns out that the OLS coefficients in a regression including a trend are the same as the coefficients in a regression without a trend but where all the variables have been detrended before the regression
- This follows from the general interpretation of multiple regressions

Computing R-squared when the dependent variable is trending

- Due to the trend, the variance of the dep. var. will be overstated
- It is better to first detrend the dep. var. and then run the regression on all the indep. variables (plus a trend if they are trending as well)
- The R-squared of this regression is a more adequate measure of fit

- Modelling seasonality in time series
- A simple method is to include a set of seasonal dummies:

$$y_t = \beta_0 + \delta_1 feb_t + \delta_2 mar_t + \delta_3 apr_t + \dots + \delta_{11} dec_t$$

 $+\beta_1 x_{t1} + \beta_2 x_{t2} + \dots + \beta_k x_{tk} + u_t = 1 \text{ if obs. from december} \\ = 0 \text{ otherwise}$

Similar remarks apply as in the case of deterministic time trends

- The regression coefficients on the explanatory variables can be seen as the result of first deseasonalizing the dep. and the explanat. variables
- An R-squared that is based on first deseasonalizing the dep. var. may better reflect the explanatory power of the explanatory variables
