PLAN

1. What Happened
in History?

2. A Theory for
Stagnation

1. What happened in History?

1. What happened in (Econ.) History?

- Not much
- Essentially, a period of low growth rates (perhaps since the 10,000 bC (Neolithic) was replaced 200 years ago by a period of high growth rates
- In the words of the Nobel-prize winner Douglass North :
 - [“If we make a new 24 hour clock for the time of civilization \(...\) the last 250 years – just 35 minutes on our new 24 hour clock – are the era of modern economic growth”](#)
- This pattern is known as the ‘ hockey stick’ (See Also Text 1, Figure 1)
- Explaining this shape is the essential question of Econ Hist

Econ Hist in 1 Graph

International dollars are a hypothetical currency used for comparison of living standards across time and space. International dollars are adjusted for **inflation within countries over time** and for **differences of cost of living between countries**. International dollars is a unit whose purchasing power is fixed, so that 1 international dollar can buy the same goods and services anywhere. Four hundred 1990 (or GK) international dollars is the subsistence minimum.

1.2 Gross world product per capita (1990 International Dollars)

“Modern Economic Growth”

Simon Kuznets,
1901 - 1985

MEG: empirical data

In aggregate terms, “Modern Economic Growths” displays three features:

- Growth in the total volume of output (from 1800 to 2020, world GDP increased by a factor of 50)
- Growth in total population (from 1800 to 2020, world population increased by a factor of 7, from c. 1 to c. 7 billion)
- Growth in per capita income (from 1800 to 2020, average per capita income increased by a factor of 10, from c. 700 to 7000 GK dollars)

(Recent concerns also brought to the fore the issue of pollution, which increases in tandem with economic growth)

“Modern Economic Growth”

Aggregate characteristics of Modern Economic Growth (MEG)

Extremely large increase in the level of economic activity

Very Large increase in the average standard of living

Large increase in population

World population living in extreme poverty, 1820-2015

Our World
in Data

Extreme poverty is defined as living on less than 1.90 international-\$ per day.

International-\$ are adjusted for price differences between countries and for price changes over time (inflation).

77%
(90% in 1800)

11%
(10% in 2019)

Low productivity = low specialization

- Natural resources constrained per capita output = low productivity
- Low productivity meant that there was little scope for specialization of the world economies
- The largest world economy in 1700 (China), foreign trade (exports of silk, china, tea, lacquer, pearls and imports of silver) represented about 1% of GDP

Low regional specialization

Prices of Meat in 8 European cities, 1500-1800

Wide price differences within the most advanced region of the world, implying lack of trade and, hence, limited scope for specialization

Source: OZMUCUR and PAMUK 2006

Low specialization = little world trade

Figure 4. *Spice and coffee mark-ups: Amsterdam vs Southeast Asia, 1580–1820.*

Why was the world poor?

- Two basic explanations,
 - With **subsistence levels** (i.e. lack of surplus, with the product of work being consumed) comes low (human and physical) capital levels. Hence, low productivity, poor infrastructure and poor technology. In other words, these are all endogenous problems to scarcity
 - On the other hand, there is an exogenous variable: **institutions**. Institutional problems lead to constant wars, imperfect markets (via monopolies or excessive regulations) or high tariffs

2. A Theory for Stagnation

The main World Economies

GDP (in million 1990 USD): India, China and Europe

	1	1000	1500	1600	1700	1820
India	29	34	61	74	91	111
China	34	27	62	96	83	229
Europe	14	11	44	66	81	159

What happened in (Econ.) History?

- The period before 1800 (or 1815 or 1820, depending on the authors) was one of overall growth
 - As measured by the real GDP (the monetary value in real terms of all goods and services produced in a given economy in a given year)
- Yet, this overall growth was not accompanied by growth in productivity, as measured by GDP per capita, which stagnated (India or China) or grew at a low pace
- Thus, GDP growth was a function of ...(see next graph)

Population (in millions)

Malthusian theory: the problem is natural scarcity

- The Malthusian Model instead states that increases in output lead populations to increased their fertility
- This increased fertility, however, is not sustainable as at some point it will clash with natural resources (food)
- When this happens, mortality will go up and population descend back to a sustainable level

Decreasing Returns

- The key assumption of the Malthusian model is that per capita income does not increase proportionally to the increase of the Q of labour (or capital)
- In an essentially agrarian economy, the increase in labour leads to a decreasing marginal output.
- This is called the 'decreasing returns'

An example of a Malthusian regime: Portugal, 1527-1850

“Portugal’s favorable circumstances by the mid-eighteenth century (...) were not to last. In the very long run, the economy conformed to the predictions of the Malthusian model. Despite variation in response to shocks, income reverted back to what could be interpreted as a long-term “subsistence” level. (...) the forces of convergence to such a steady state did include endogenous fertility and mortality responses in the spirit of Malthus” (Palma and Reis, 2019).
