In both institutional and private practice settings, health-care professionals are inundated with evidence-based clinical practice guidelines often based on decontextualized evidence from randomized clinical trials. Health professionals do not doubt the foundation or efficacy of a particular guideline but may decide that it is not relevant or *effective* for treating the patient before them at that particular moment. In other words, the usefulness of decontextualized evidence is limited for clinical decision-making. Furthermore, clinical practice guidelines from various disciplinary sources may provide varying or even conflicting guidance which needs to be interpreted and reconciled for individual patients. A solution to this dilemma is the participatory production and/or implementation of practice guidelines that derive their evidence base from the actual practice settings in which they are meant to be applied. Even where clinicians' input into the production of therapies and procedures is not possible, their full engagement in the means of putting the evidence into action—in other words, participatory implementation—will greatly increase their relevance and contextual applicability. Sensitivity to contextual practice needs turns evidence-based practice into *evidence-informed* practice. Examples of efforts to create and implement setting-sensitive, evidence-informed guidelines exist from various institutional settings, including hospital emergency rooms and intensive care units, as well as more generalized guidelines applicable to both primary and specialized care in mental health, addictions and chronic disease management.

Patient-Centred Health Services Planning and Delivery

Proceeding from the above discussion of clinical practice needs is the need for contextually sensitive

and adaptable, evidence-informed guidance for the co-management of health care by patients and providers. The contemporary move towards patient-centred medicine and clinical co-management requires the creation and implementation of knowledge that is comprehensible across a broad spectrum of health literacy levels and which is adaptable to the individual needs of patients and their lived lives. The usefulness of decontextualized evidence is doubly limited for clinical decision-making involving patients and health-care providers, particularly in primary care settings where all parties are often dealing with multi-morbidity and complex life issues. Action research provides a solution through the co-production of evidence-informed guidance which is robust enough to generate action plans that are sensitive to individualized needs. Examples of this include the adoption of a participatory research approach within practice-based research networks, where individual clinics are seen as communities of practice, generating setting-specific knowledge that is then generalized through consolidation within the larger research network. Participatory Action Research approaches have also been undertaken for patient-centred care in, among other areas, mental health, chronic disease management, dental care and multi-morbidity.

Community-Based Health Promotion

Historically, geographically or ethno-culturally defined communities had been the targets of top-down, academic-driven research. Researchers would identify a health-related gap in a given community setting and propose, fund, design, deliver and evaluate interventions to address it. This form of community Intervention Research has been termed *helicopter research* by affected communities who had often served as little more than test or data extraction sites, while receiving little or no direct benefit and most often never hearing from the researchers once the study was completed. Since the 1980s, however, self-identifying communities have increasingly mobilized to identify and address pressing health issues, with or without external academic support. Community-based health research is founded on the action research principles of participatory need identification, mobilization and evaluation, coupled with capacity building, empowerment and community ownership of the entire process. Research topics may originate solely from the community or from academic or other observers; but the topic must meaningfully resonate with or meet the real needs of the community in order that it values the research process enough to take ownership and ultimately sustain its effects. CBPR has most often taken the form of participatory Intervention Research, creating programming that addresses health behaviour issues and

builds on pre-existing strengths at the community level (i.e. primary prevention). In this way, it has addressed, among others, issues of obesity and chronic disease, notably diabetes and heart health, as well as HIV/AIDS prevention and service delivery, addictions and mental health. The CBPR approach has also been used in assessment or exploratory studies aimed at creating a better baseline understanding of certain community issues, often as a precursor to co-developing health-promoting action. These studies have used various research designs (observational, exploratory, quasi-experimental and experimental) and employed qualitative, quantitative or mixed methods. The fundamental participatory factor is that the community has taken ownership of the process, has identified the issue or need, is methodologically involved in creating and interpreting the new knowledge and is committed to the implementation or dissemination of the findings.

Evidence-Informed Public Policy

The 1986 Ottawa Charter for Health Promotion called for a shift away from public health policies and programming that addressed individual behaviour towards those that addressed the upstream social determinants that constrained individuals' opportunities to make healthy choices or have access to health services. By addressing and realigning the social and economic forces that placed a higher burden of risk and ill-health on vulnerable populations, health promotion attempted not just to increase the mean health of the population but also to create *health equity* by ensuring that the well-off did not get healthier at the expense of the vulnerable, underserved or less well-off. Community empowerment became a central tenet in this movement, with a greater role for community and citizen involvement in the identification of population health promotion needs and the means of addressing them. Over the ensuing years, this has been applied inconsistently and with mixed results. Although local and regional public health planners have attempted to engage communities, they and national agencies have most often failed to move beyond top-down planning and implementation and have largely continued to address individual behaviours or measure success through individual-level outcomes. Those efforts that have successfully engaged with communities have adopted modified CBPR approaches that include community leaders and community-based organizations, along with public health policymakers and academic researchers, to identify and address population health issues and their upstream determinants. Examples of participatory public policy programming are most often to be found around issues emanating from well-defined and sufficiently mobilized communities, such

as is the case with indigenous health and HIV/AIDS policy programming.

Medical/Health Professional Education Reform

Although physicians and other health-care professionals are rigorously trained in evidence-based practice, many find that they lack the cultural competence or sensitivity to deal with patients or issues outside their immediate experience. Some of the blame has been laid on an education system that often does not value diversity and rarely attempts to expose professionals to environments outside controlled clinical settings. This has led to the underservice or disservice of indigenous peoples and vulnerable populations, including immigrants, those living on public assistance and the homeless. Participatory curricular reform is a movement to bring together members of vulnerable communities with professional orders and academic curriculum developers to reform the way undergraduate and graduate students in the health professions are trained. Examples of this include creation of indigenous health curricula to expose medical students to the specific cultural-historical context in which they will ultimately be treating indigenous patients and service delivery placement opportunities for students and interns to work among various vulnerable populations within community clinics. Many of these efforts have been evaluated and have been shown to increase service providers' sensitivity and lower incidences of mistreatment or refusal of service.

Conclusion

At all levels—clinical, community and population—action research in health has attempted to merge the best available evidence with end-user experience and contextualization in order to create effective change. The inclusion of the end users and beneficiaries in the production of new action-oriented knowledge, be they patients, health-care providers, communities or policy-makers, has helped ensure that treatments, procedures, interventions and programmes have met the actual needs of those who must deliver or receive them.

HEALTH EDUCATION

Health education encompasses a variety of planned learning opportunities and experiences aimed at fostering knowledge, empowerment and skills in individuals, groups or communities, so that they may make decisions about and take actions to improve their health. Deemed an important component of health promotion, health education may focus on conveying information regarding risky personal behaviour and other risk factors which can be changed or avoided through lifestyle modifications in diet, exercise and other behaviours that have an impact on health and through access to the health-care system. Health education may also impart information on social, economic and environmental conditions that have a negative impact on health so that action can be taken to render them more conducive to good health. Health education can occur through educational institutions, health-care providers, interactions with others, exposure to the media and social marketing and action research.

Action research combines theory, education and action to address organizational, community and social issues with the involvement of those who experience these issues so as to improve understanding and practice. It provides a rich, collaborative learning environment where health education takes place through transformative learning. Through its participatory approach, its emphasis on dialogue, its reflective process in learning and its focus on action, action research fulfils the empowering and enabling goals of health promotion and reflects the current transformative learning trend in health education. Transformative learning takes place when individuals develop the critical

consciousness to deconstruct prevailing ideologies; recognize the social, political, economic and personal constraints on freedom and realize that they have the power and agency to challenge and act to change social conditions and structures of power. This transformative learning is health education aimed at enabling individuals, groups and communities to increase control and take action over their health and its determinants.

The origins of health education as a component of health promotion are presented, followed by its link to action research through a health promotion approach that embraces the social determinants of health and through transformative learning that takes place in such settings, leading to individual change and ultimately to social change for better health. Future research directions are also discussed.

Origins

The 1970s marked an important turning point in health education with the realization of the limitations of medicine, pressures to reduce medical costs and a social and political climate which professed individual control over health. The Lalonde Report from the Government of Canada in 1974 and the US Surgeon General's *Healthy People* report in 1979 both discussed the role of individual lifestyle and personal behaviour in influencing health and expanded this view of health to include the role of environmental factors and social conditions in affecting health. In 1984, the World Health Organization Regional Office for Europe defined health promotion as 'the process of enabling people to increase control over, and to improve, their health' and included strategies such as changes in institutions, legislation and policy in addition to lifestyle and behavioural changes. In 1986, the Government of Canada released the Epp report, *Achieving Health for All: A Framework for Health Promotion*, which identified self-care, mutual aid and healthy environments as health promotion mechanisms. In the same year, the First International Conference on Health Promotion led to the Ottawa Charter for Health Promotion, which identified five key action areas: (1) building healthy public policy, (2) creating supportive environments for health, (3) strengthening community action for health, (4) developing personal skills and (5) reorienting health services.

In this new era of health promotion, which recognized that health was influenced by factors beyond medical care, health education took two directions. First, it focused on promoting changes in behaviour and lifestyle to foster optimal health, with the assumption that individuals have power and agency over personal decisions and actions regarding their diet, exercise and other behaviours and that these changes can lead

to better health. Second, health education strategies targeted changes at the institutional, legislation and policy levels to foster social conditions conducive to health, in keeping with the environmental model of health promotion.

Early health education emphasized lifestyle and personal behaviour change and the reduction of risk factors for disease, which did not adequately consider individuals' capacity to respond to or act upon their health, given the environmental challenges they may face. It reflected the values systems of liberal nations, which embrace individual responsibility for one's successes and failures, and tended to overlook the underlying social conditions which influence individual behaviour and ultimately have an impact on health. For example, an individual's social class has long been established as an important, if not *the* major, risk factor for disease. Since a state's approach to public health is reflected in its policy, health promotion which emphasizes the social determinants of health can influence policy and foster social conditions conducive to health for all. In 2005, the Bangkok Charter for Health Promotion in a Globalized World revised the definition of health promotion as 'the process of enabling people to increase control over their health and its determinants, and thereby improve their health', to punctuate the social determinants of health. However, the Bangkok Charter has been criticized by the People's Health Movement and academics for diluting the democratic language of the Ottawa Charter and reverting back to and reinforcing the emphasis on individual responsibility.

The terms *health promotion* and *health education* have often been used interchangeably. Some draw a distinction between the two terms, stating that health promotion encompasses a combination of health education and health advocacy. Given that health promotion has evolved into a strategy that reaches beyond lifestyle and behaviour education to include acting on the social determinants of health, health education has a role to play in creating social conditions conducive to health for all. This social justice approach, which strives for health equity, blurs the distinction between health education and health advocacy, since health education strives for social change. Health education can influence political, economic and personal decisions by educating policymakers, mass media and other influential sources and advocating for healthy public policy, environments, attitudes and behaviours; by fostering the empowerment of individuals, groups and communities who have been disproportionately affected by morbidity and mortality; by cultivating the importance of both experiential expertise and inter-sectoral collaboration for action and by provoking critical understanding of the underlying causes of inequity. Health education can incorporate processes

for communities' meaningful participation and control, thereby encouraging their empowerment through gaining understanding and control of personal, social, economic and political forces and actions to improve social conditions. Health education can achieve this emancipatory objective through action research.

Health Education and Action Research

Action research arose as an innovative approach to address the limitations of social research to result in improvements in practice. In health promotion, action research promised to narrow the apparent research/theory/practice divides. With the realization that health education needed to go beyond promoting changes in personal behaviour and lifestyle and the recognition that social conditions influence the ability of individuals, groups and communities to make decisions and take action to improve their health, it became clear that oppressive social conditions that render some groups more vulnerable to poorer health needed to be addressed. Action research conducted from a critical and emancipatory approach attempts to study and reduce health inequities through the democratic participation of those affected by them. It assumes that truth is found in and created through relationships of power and that what is accepted as known is that which those in power declare. It also assumes that knowledge is socially constructed, historically situated and based on values and places this context at the centre of the research process. Knowledge is influenced by each individual's background, context and understanding of his or her social position related to intersections of gender, race, class, sexual orientation, culture and other factors. People thus make sense of their experiences through the dominant ideology and from their contextual position in the structures of dominance. A critical and emancipatory approach challenges societal beliefs, assumptions and perspectives; brings attention to and scrutinizes the relationship between social systems and individuals; uncovers the sources and dimensions of inequities and focuses on the empowerment of human beings to overcome and transform structural disadvantages.

Action research conducted under the critical and emancipatory paradigm views knowledge production as an emancipatory act. It places critique at the centre of knowledge production and aims to cultivate a critical ability to question, deconstruct and reconstruct knowledge in the interest of emancipation. Critique is aimed at systemic and institutional structures, their creation and how they may be changed to minimize or eliminate their oppressive effects on certain groups. Under this paradigm, action research seeks emancipation both within the research process and within

society. This goal is realized through a transformative knowledge production process.

The collaborative approach of action research creates a privileged site for transformative learning. Core elements of transformative learning include individual critical self-reflection, conscientization and empowerment as well as group processes and relations that foster co-learning in dialogue and shared power and decision-making. Conscientization or critical consciousness occurs when people develop critical skills and come to recognize their role in changing their social conditions. It leads to empowerment when individuals develop these skills, gain mastery over their lives and improve equity and quality of life. Co-learning occurs when all partners exchange information, learning, experiences and perspectives and develop a deeper understanding of each other and of the phenomenon at hand. For co-learning to take place, partners must collaborate to create an environment of trust and mutual respect and openly acknowledge, discuss, challenge and realign power imbalances through a more equitable definition of roles. Partners must commit to a process of self-reflection and cultural humility to recognize their cultural beliefs and assumptions and break through stereotypes which may be preventing them from being sensitive to another's culture. They must work within each other's different agendas and politics and embrace the discomfort that comes with the acknowledgement of the economic, social, cultural and gender inequities that are at the root of oppression. Through this process, they come to understand power relations and redress power imbalances towards equity.

Health education that adheres to the principles of health promotion encompasses addressing social, economic and environmental conditions that affect health by fostering environments where action can be taken to change social conditions to render them more conducive to good health for all. In the context of action research, health education takes place through the transformative learning process, which leads both to individual transformation and ultimately to social change to create a more equitable society. More research is needed to better understand the relationship between action research and transformative learning in order to adopt a more informed health education practice. The effectiveness of achieving improved health outcomes through this approach to health education also needs further investigation.

HEALTH PROMOTION

Participation in decisions that affect one's health is a fundamental concept in health promotion. It is built into the widely recognized definition of health promotion from the Ottawa Charter: 'Health Promotion is a process of enabling people to increase control over, and to improve, their health'. Enabling people to increase control over the factors affecting their health has led to much work in the health promotion field on processes of participation from the individual to the societal level. Thus, health promotion is a good fit with the basic principles and processes of Participatory Action Research (PAR). Both focus on action and value participation and empowerment, as well as giving voice to those with less voice in decision-making processes. This entry will describe how participatory processes are integral to health promotion and how PAR is used by health promoters. The skills required of health promoters that are congruent with PAR are described. The challenges of using PAR in health promotion are discussed, and some ideas about future directions are stated.

Health Promotion Basics

It has been known since the Alma Ata declaration in 1978 that participation in decisions improves one's health. Having that sense of control is a direct contributor to one's health, as well as enabling individuals and communities to advocate for changes to situations that are bad for health. For example, direct discussion with caregivers about one's health care can lead to faster recoveries, and families working together can advocate for soil testing and removal when their children show signs of lead poisoning. Although health is affected by individual behaviours like smoking or physical activity, it is also affected by socio-economic policies and conditions in the environment that are beyond individual control, such as lead in soil or poverty. Health promoters rapidly recognized the importance of socio-economic policies and the environment and that creating supportive environments for behaviour change and changing policies are health promotion strategies. The first three major strategies in the Ottawa Charter recognize the importance of involving community members in addressing the broader policy issues through 'Building Healthy Public Policy', 'Creating Supportive Environments' and 'Strengthening Community Action'. Engaging community members in actions to improve their health often means working with the most marginalized and those with the weakest voices in political processes. For example, residents of a high-rise apartment building in Toronto did not like the drug dealing happening in the lobby of the building, so they met as a group (many for the first time) and brainstormed possible solutions. They organized community functions in the lobby in front of the elevators for families in the building, thereby creating an environment unsupportive of drug dealing and strengthening their sense of community. These are examples of health-promoting strategies built around participation.

PAR in Health Promotion

PAR is a natural fit for health promoters. It requires participatory processes, connects research directly to action and focuses on giving voice to those usually excluded from research and decision-making. PAR's espoused processes enable participants to create and share experiential knowledge and then work together to take action. PAR could be seen as a type of health promotion intervention. Through direct involvement, participants can be part of the planning and creative process from the beginning, including the determination of the data collected, interpretation and actions to take. The problem of how to 'disseminate' the research is non-existent—participants already know what to do with the results. This connection between action

and research is what health promoters strive for in all interventions.

From a research perspective, what do health promoters want to know? At a very basic level, they want to know how individuals, communities and societies change and what interventions work best. There are many theories of change at each of these levels that provide guidance for health promotion interventions, and much has been learned from traditional research methods. However, health promoters also find that contexts vary a great deal, and it is necessary to talk to those in the communities about what works for them and use a range of strategies at individual, community and societal levels. The experiential knowledge of community members is important to understand for the successful implementation of programmes and for successful community-relevant research. For health promoters working in community settings, PAR becomes a research method of choice, especially when working with people isolated and marginalized from mainstream society for a variety of reasons.

Healthy Settings

One of the best examples of multiple health promotion strategies working together using participatory methods is the Healthy Settings movement. The World Health Organization has endorsed particular criteria that schools or communities need to meet to be designated as a 'healthy school' or 'healthy community'. These criteria state that planning for healthy municipalities, communities, schools, workplaces, hospitals or islands requires the participation of all stakeholders to envision a positive future together and generate ideas about solutions and next steps that address individual to policy actions. For example, in a healthy school planning process, principals, teachers, students, parents, school staff and surrounding community members need to be involved. In many cases, academic and community researchers have assisted in needs assessments and the development of actions in healthy settings through using PAR methods.

Skills Required for PAR and Health Promotion

The rigour of PAR requires its practitioners to be reflexive about their role and values and how they affect the research process and to have interpersonal skills so that they can facilitate participative processes. Reflexivity is a useful but underutilized aspect of health promotion practice and represents a relatively new area of focus in the published literature. The ability to facilitate community engagement processes is a carefully crafted skill that is part of the training of

health promoters in some programmes in Canada. PAR can help health promoters be reflexive and enable practitioners to understand their role and values. True PAR requires humility on the part of the researcher and an ability to treat community members as equal partners in research. These qualities fit in with a community-based health promotion practice, which also requires respect for others and a willingness to empower and enable others to take control. This is also consistent with health promotion values of social justice, equity and local autonomy.

Challenges of Using PAR in Health Promotion

Despite the natural fit between PAR and health promotion, there are few examples of PAR with direct reference to health promotion in the published literature. There are three main challenges to seeing a stronger connection in the literature: (1) the desire by health promoters to be recognized as legitimate in the health field; (2) the wide range of interventions and theories in use in health promotion, some of which are more amenable to biomedical research methods, and (3) the political nature of health promotion practice. The health field has been dominated by the medical model and research paradigms that have epidemiological, clinical and economic/administrative origins. In its attempts to gain legitimate status within the health field, health promotion has tried to show its value through the use of those methods. When health promoters are engaged in community development and advocacy, it has been an uphill battle to prove the worth of these interventions using the gold standard research method—randomized controlled clinical trials. The participatory basis for health promotion work has contradicted the use of randomized controlled clinical trials as the gold standard for research and evaluation. In addition, the need to adjust tools and interventions to the individual and community contexts and the focus of health promotion on actions to change political and environmental contexts challenge the role of traditional research methods that try to maintain a constant context in order to study the intervention. The requirements of journal publishers and academic reviewers in the health field have also made it difficult for health promoters to use PAR and get their work published. Those with more success have published in the education and community development fields.

Due to the breadth of practice of health promoters, from those who specialize in individual behaviour change and health education to those involved in community development and changing public policies, there is a range of appropriate research and evaluation methods. With this in mind, PAR is not suited to every aspect of health promotion. Natural experiments,

quasi-experimental methods and realistic evaluation methods are being used in health promotion research and evaluation.

In addition, it is important for health promotion practitioners to recognize that participation has many forms and only some of them match the highest standard of PAR: participation in all phases of the research process. Given the range of health promotion research practices, there is a range of levels of participation. For example, health promoters use collaboration or coalition building as a strategy to work with all stakeholders that affect or are affected by a policy such as transportation. Bringing such stakeholders together is a form of participation, but it is also very political. Participatory processes used by health promoters frequently challenge established authorities (government or organizations) through encouraging collective action towards change, and such actions are limited by what is feasible in the context of certain government and organizational mandates. PAR can help bring legitimacy to such actions, but there may be limits on the 'purity' of the participation.

Future Directions

In summary, health promotion is a good fit with the basic principles and processes of PAR. Both focus on action and value participation and empowerment as well as giving voice to those with less voice in decision-making processes. Although the uptake in the formal literature is minimal, the use of PAR in undocumented health promotion practice is possibly more widespread. At the same time, there are a couple of factors driving health promoters to publish about their use of PAR—an increasing recognition of the need to adapt to a rapidly changing context and the pressures to focus on social justice, equity and the social determinants of health. PAR can provide a research process to assist the health promotion practitioner in developing and adjusting interventions to be more culturally and socially appropriate. Above all, PAR is a method that matches the working style and value base of health promotion.

HEGEMONY

Hegemony is a broad movement towards domination of certain groups through means of coercion and other non-physical forms of control. A concept generated by a number of Marxist thinkers in the early twentieth century, hegemony represents a modern form of oppression in which the forces in power obtain the acquiescence of the oppressed through deception, assimilation and social reproduction. Hegemony is propagated through the fundamental structures of society in order for the very culture of certain groups to be laden with attitudes and beliefs that foster their exploitation. The Italian Marxist Antonio Gramsci developed the purest conception of hegemony, which subsequent scholars have expanded, at great length, into the current theory, which is now refined and applicable in numerous situations. Action researchers, drawing upon critical theory, can work with participants to uproot the ties of hegemony and construct a society less encumbered with ideological forms of dominance.

Marxian Theory's Precursory Formulations of Hegemony

Although the roots of understanding hegemony can be quite varied, Karl Marx laid the foundation of contemporary hegemony theory in numerous ways. As a critical theory that seeks to unveil capitalist exploitation, Marxism operates as a framework towards exposing imbalances of power, particularly among social classes. Most notably, Marx' theories regarding ideology serve as a crucial basis for hegemony. Ideology represents a system of thought that is transmitted among a group of people, and while there are several purposes and functions for ideology, one clear aim of capitalist ideology is to both control and pacify the working class. Marx

anticipated the concept of hegemony when he argued that the world view of the bourgeois would, through capitalism, become the dominant world view of society, and his theories regarding base and superstructure would serve as the clearest precursor to the hegemonic process, so clear, in fact, that Gramsci would utilize a variant of this paradigm in his own writing. In discussing the idea of base, Marx was referring to the material forces of society, especially the physical forces of production. These forces do not occur in isolation but instead are mediated by ideological and cultural superstructures. These superstructures refer to largely non-material forces, like ideology and hegemony, which inform the nature of production and steer the exploitative reins of capitalism.

Marx was not the only theorist who influenced Gramsci's powerful conception of hegemony. Vladimir Lenin and other Leninist theorists would prove to be among the first to offer an analysis of hegemony but would do so in a manner different from how hegemony is typically conceived. Drawing inspiration from Marx, Lenin and others would discuss hegemonic forces in an ideological fashion; however, these theorists were more fixated on how hegemony could be functionalized as a revolutionary force in discussing the 'hegemony of the proletariat'. Similar to the Bolshevik concept of the 'dictatorship of the proletariat' as a governmental force, the hegemony of the proletariat would link to a system of ideas that would unite the peasant class under the leadership of the proletariat in order to combat the dominant ideology of the bourgeois class. Leon Trotsky, a notable contemporary of Lenin, also spoke of how the hegemony of the proletariat should serve as the epistemology to provide the government direction. These discussions of hegemony, while certainly valuable, would prove ultimately unfruitful in the actual practice of the Soviet government, and the radical reimagining of hegemony performed by Gramsci would, in some sense, demonstrate why the hegemony of the proletariat never came to fruition.

Gramsci's Expansion of Hegemony

Antonio Gramsci's concept of hegemony is among the most important contributions within the critical theory tradition and was largely composed in a prison in Rome. The canonical *Prison Notebooks* were crafted between 1929 and 1935, when Gramsci was imprisoned by the Italian Fascist government, and these stressful conditions undoubtedly influenced the nature of the texts, which Gramsci could not edit, refine and formally publish. Gramsci's theory of hegemony also suffers, in a sense, from the conditions in which it was engineered, proving to be somewhat fragmentary and less comprehensive than many are led to believe.

Nevertheless, the subsequent decades have witnessed numerous scholars interpreting Gramscian hegemony and establishing a necessary connectivity within his thought, which now exercises significant influence on many scholars in sociology and education and those working in critical theory.

What is immediately striking about Gramscian hegemony is the role of culture as both an oppressive and a liberating force. In contrast to the Marxian usages of hegemony, which were primarily fixated in the realms of economics and social class, Gramscian hegemony is a cultural hegemony that goes beyond economics and thus is far more pervasive. Gramsci was writing against the Italian Fascist regime that was in power prior to World War II, and in examining how this regime both came into power and maintained its control, Gramsci postulated that cultural hegemony served a crucial role. Although initially a cultural minority, groups like the Italian Fascists could gain power in pivotal centres of cultural capital within a society, like the government, the media and educational institutions; moreover, those groups could form alliances with other groups and exert a hegemonic force that could pervade an entire culture. Certainly, expressions of physical dominance were possible, but the true power of cultural hegemony lay within the ability, often through manipulation, to obtain the consent of the oppressed to further enforce oppression. Similar to Foucault's theories regarding forces of discipline, hegemonic forces operate with a cruel efficiency in which knowledge and culture become ideological weapons that hold legitimate material implications.

These material implications are most significant for the *subaltern* social class, a term first utilized by Gramsci and then appropriated by theorists working with hegemony as well as post-colonial scholars. In using the term *subaltern*, Gramsci once more expanded the critical framework to incorporate more groups of people instead of focusing primarily on the economically determined proletariat. Depending on its usage, the subaltern social class is the primary target of hegemonic forces, a dominated group whose epistemology, history and access to political and economic power are controlled by the dominant class. What proves striking about Gramsci's form of subalternity is how it is the product of hegemony. The subaltern class exists in a culture outside its choosing, and attempts to exist outside the hegemony are met with stricter control. While the subaltern class is victimized in hegemonic systems, the subaltern, in the Gramscian sense, still possesses potential as a revolutionary subject capable of transforming the system.

Gramscian hegemony is a difficult concept to grasp for many scholars and theorists, and some of its central ideas are often misunderstood. The primary reason for

this misunderstanding lies in the immaterial nature of hegemony, which lends itself to any number of interpretative lenses. However, a few stabilizing distinctions should be made clear. First, although Gramsci was examining hegemony to criticize a fascist regime, *hegemony* and *totalitarianism* are not interchangeable terms. This further complicates the perspective on hegemony, for instead of a static, totalitarian concept, hegemony is a rather fluid process that is continually changing to serve the needs of the dominant social group. One contemporary example of this hegemonic revision can be seen in the Internet, which was once an alternative space where no forms of advertising were permitted but gradually became a tool for capitalism and now serves as one of the primary means to enforce several hegemonic structures, particularly those of corporations. Nevertheless, the dynamic nature of hegemony should not be conceived as a comprehensive veil that covers an entire society. Instead, pockets of counter-hegemonic activity are a constant presence within hegemony. Simply because a group of individuals acquiesces to the hegemonic leadership of a dominant group does not necessarily mean that they do so happily. Indeed, Gramsci was aware of citizens' antagonistic attitude towards hegemonic groups and structures, which could stimulate action that could disrupt the processes of hegemony. Unfortunately, the constantly evolving nature of hegemony, its pervasiveness within a given culture and the fragmented nature of counter-hegemonic action usually enable the dominant social order to maintain hegemony and exert continual influence over the majority of individuals.

Contemporary Hegemony

The English translation of *Prison Notebooks* was published in 1970, and since that time, many have argued that theories regarding hegemony have lost relevance in contemporary society. Critics of Marxism, particularly those who align themselves with postmodern philosophy, argue that hegemony contributes to a false meta-narrative that no longer accurately describes the world. However, a strong contingent of critical scholars contends that hegemony, through globalization and technology, has increased substantially into numerous avenues. Most notably, the prevalence of a Western, specifically American, world view has acquired increasing dominance globally. The 'Americanization' of the world has manifested itself through the pervasiveness of the English language in much of the industrialized world, the increasing American corporate presence in other countries and the spread of American values and attitudes, typically centred upon consumption. While the oppressive nature of this changing landscape is open to debate, the notion that the cultures of

various countries are being supplanted by a dominant world view demonstrates the further need for studies in hegemony as hegemonic forces operate at both local and global scales.

Action Research and Hegemony

As a methodology that often ventures into critical theory, action research can serve as a counter-hegemonic process. A pivotal inspiration to action research, Paulo Freire expressed an educational philosophy firmly rooted in counter-hegemonic theory. First, Freire was critical of traditional modes of education that sought to broadly instill a knowledge constructed by the dominant social order that reproduced the unequal social hierarchy. Second, Freirean concepts like conscientization and communal knowledge construction worked to undo the hegemonic forces in education. Action research can further variations of Freire's work in any number of fields for many action researchers not only possess an understanding of hegemony due to their study and research but can also work with their participants to collectively dismantle hegemonic power in communities.

Indeed, Gramsci, among others, argued that intellectuals held a significant role in promoting both hegemony and counter-hegemony. Working at the vanguard of cultural exploration and creation, intellectuals have access to knowledge that can be utilized to either enforce hegemony or disrupt it. Once more, hegemony is perpetuated by cultural institutions like schools, universities and media outlets where the educated citizenry hold positions of power. While the majority of these intellectuals are mired in the processes of hegemony and further hegemonic principles, those who are versed in critical theory and seek to work towards a more egalitarian society can expose hegemony and mobilize individuals towards counter-hegemonic action. Gramsci advocated a Marxian concept known as praxis, in which theory and action blend together in order to better society. Action researchers, with their knowledge of theory and methodology and their commitment towards actualizing their research, perform their own version of praxis, which in turn can be linked to counter-hegemonic efforts, particularly in education but also in the community.

Finally, apart from operating as counter-hegemonic practice for marginalized populations, action research functions as an alternative to the hegemony within research methodologies. There is a dominant epistemology within research methodologies that could be labelled as hegemonic, that potentially limits the democratization of knowledge. With the majority of researchers consenting that their research operate within narrow constraints, traditional research methodologies

are informed by hegemonic structures, and these structures can lead traditional research away from the public good while restricting researchers from truly exploring their interests or those of the community. Action research provides a tenable alternative for researchers who wish to work outside the hegemony of the academy in order to access new methodological possibilities, perform research as a public good and effectively change their institutional culture.

HERMENEUTICS

Philosophical hermeneutics is concerned with interpretation and understanding. For many centuries in Western thought, hermeneutics was confined to the science of the exegesis of religious texts, but it broadened with the nineteenth-century efforts to formulate a theory and method of interpretation. In the twentieth century, Martin Heidegger (1889–1976) and Hans-Georg Gadamer (1900–2002) developed the philosophy of hermeneutics to challenge metaphysical certainty, finding it a powerful ontological mode of being-in-the-world-with-others.

As a philosophy that emphasizes the role of history, language and provocation in all human understanding, Gadamer's hermeneutics offers a philosophical underpinning to action research. He argues for the primacy of inquiry as an essential human trait and elucidates the elemental role of dialogue and iteration in inquiry. This entry outlines the origins and development of hermeneutics, focusing on Heidegger and most particularly Gadamer's contribution to its development. It elaborates

on four concepts central to a hermeneutic standpoint: (1) effective history, (2) prejudice, (3) provocation and (4) fusion of horizons. The part played by each of these concepts in action research is considered.

In Search of Method

It was the theologian Friedrich Schleiermacher who in the early nineteenth century expanded hermeneutics beyond its role in interpreting religious texts. Observing that it is never possible for a reader to understand all that is said by a text that is posing difficult ideas, Schleiermacher developed a maxim that it is misunderstanding that naturally arises in encounter. He proposed the need for a theory and method of interpretation—hermeneutics. He sought and failed to find a hermeneutic method, unable to apply truth-rules that would overcome the divinatory nature of the dialogue that he had found at the foundation of human understanding.

Following his lead, Wilhelm Dilthey in the late nineteenth century also sought a method that would be specific to the art of interpretation—one that would permit an objective reading of symbolic structures in human life. Dilthey came up against the same problem as Schleiermacher—that the phenomenon of understanding exists before and is the ground for method. Understanding does not arise from method.

Ontology of Understanding

The problem was overcome in the mid twentieth century, when Heidegger proposed that understanding is ontological, a mode of existence. In *Being and Time*, published in 1927, he posits that human being-in-the-world is inescapably finite, and we see and learn from where we are positioned, where we have been thrown. Our knowledge is utterly insecure. We search for universal and comprehensive truths and methods, but these are chimeras. Instead, we are always struggling to build understandings. Our meanings are always greater than the logic of our words and propositions. When a carpenter makes a logical statement about a hammer being heavy, for example, the meaning is only partially that it has the property of heaviness. The meaning could also be 'I am tired', 'Please help me' and much more. Heidegger allows people to see an 'unending struggle to find words for all that should be said in order to understand themselves' and argues that they dwell in the world in language.

Gadamer took up the hermeneutics of being and language from his teacher Heidegger, and three decades later, in 1960, he published his masterwork *Truth and Method*. A pragmatic view of why an understanding of understanding is important, the work shows that people always seek to know something useful here and now.

But he also aims to overcome the hubris of assuming that people can accomplish objective knowledge of the phenomena that concern them, particularly those in social and human realms.

Scientific method is applicable to natural phenomena because it builds arguments based on norms and standards built in a particular tradition. Causal laws 'impervious to changes in vantage point' are discovered because the world of objects is conceived accordingly. The humanities, however, defy theoretical universality because they concern an infinite number of positioned and ever-developing perspectives. They defy the methodological certainties of the natural sciences. The hermeneutic phenomenon, Gadamer explains, is not a problem of method at all. It is a question of understanding how understanding happens.

Key Ideas

Essential to an appreciation of hermeneutics and to their use in action research are four key ideas: (1) effective history, (2) prejudice, (3) provocation and (4) fusion of horizons. These are elaborated in the following sections.

Effective History

Philosophical hermeneutics outlines the conditions of the possibility of understanding. These conditions are located in the traditions to which interpreters belong and in the authority of those traditions. In *Truth and Method*, Gadamer sets out to show that understanding is never a subjective relation to a given object but to the history of its effect. For human beings in discussion with one another or with a text or work of art, the effect of history is always at work. The language we have learned and the context from which we come sets us in a horizon of meaning. The starting point for understanding is always the whole of the history that lies behind people and is effective in each one of them, in their language and collectivities. Tradition opens some perspectives and closes others, and language (in all its forms) always mediates their access to the world. Aware of this finitude, they become aware of how their tradition and language are ceaselessly open to new experience and interpretations. The starting point is expectations and assumptions: prejudices.

Prejudices

People in different cultures at different times proceed on the basis of what they have already understood, expressed in the language they have learnt, but are ready to expand their knowledge. To the extent that their understanding of the world is founded in this way, they are prejudiced in that they already possess

predispositions: orientations towards, and languages for, whatever it is they are seeking to understand. Therefore, prejudice is not negative or unproductive but a starting point for learning. That each consciousness has a different starting point is a basic ontological mode of being, being one among many, each one distant from the others yet endlessly bound in conversation with others. From a hermeneutic perspective, prejudice proves to be highly productive. Prejudices form a horizon from which each person may move outwards in encounter with the world. In dialogue, prejudices are foregrounded and brought into question—it is the mode by which individuals learn and change. Mostly, people do not notice how their prejudices are brought up short by the propositions and apparent meanings of others, but it is a constant occurrence. When they encounter people who are very different or stories from an alien past, they are noticing that they see or saw things differently, and they are asking why. And are they right?

Provocation

Understanding is an event. It is an encounter of prejudice (which has provisionally been concluded) and the propositions of interlocutors. How, then, does one interpret distant, different or subaltern voices in a way that one is able to hear their claims for or on one? It is not, as some have suggested, a case of putting oneself in their shoes, being neutral with respect to what is being said or extinguishing oneself—all of which are impossible. Instead, the person who understands something is the one who foregrounds her own foremeanings and prejudices and brings them up against that which she hears, sees or experiences. Provocation is the experience of understanding. When this happens, people are participating in meaning with the other.

When individuals are coming to an understanding with one another, they find themselves strengthening the other's argument. They attempt to make what they hear make sense in their realm. They try to see how the parts of what they say are aligned with the whole of what they seem to mean. This phenomenon is known as the hermeneutic circle. Georgia Warnke lists three elements to this event. First, they are prepared for a text or the person to tell them something that they did not already know; they accept alterity. Second, they align the part with the whole, projecting meanings in their attempt to understand on the basis of expectations they already have. Third, they give the speaker a chance to mean something to them by assuming that what is said is or could be true.

Fusion of Horizons

The horizons of understanding expand when people not only identify the way in which things from the past or from other people are different but also when they

ask how they can be combined with or otherwise affect their current understanding. Their horizons partially fuse with those of the other. In the process, even if they are disagreeing with what they are hearing, their perception of the world changes, as does their understanding of themselves. They accumulate, reject and amend, remember and forget meanings. Over time, language changes: Words, images and sensations change, as do linguistic structures and whole language systems. Consequently, they change as human beings, taking the ground of new understanding with them.

Critiques of Philosophical Hermeneutics

As the thinking of Gadamer and his school spread across the Western intellectual world, a number of critiques were levelled, many of which served to hone the hermeneutic argument. Jürgen Habermas accused hermeneutics of excessive reverence for tradition and failing to offer emancipation and critique of ideology. The hermeneutic school responded with scepticism, arguing that pure emancipation was a utopian, Enlightenment illusion not grounded in real experience. Emancipation, such as it is, is already implicit in the hermeneutic encounter.

A second criticism challenged ideas of openness and hermeneutic sensitivity as a relativistic lack of standards and unquestioning deference to understandings different from their own. Warnke is one hermeneuticist who refutes this, using Gadamer's point that while meaning making involves a fluid, ever-shifting multiplicity of possibilities, it is not without reservations. Making meaning is not a relativistic, wholly subjectivist process but one built on sense and prior understandings. The hermeneutical task is always a questioning of things.

Jacques Derrida criticized hermeneutics as assimilationist—always attending to the achievement of understanding and the continuity of tradition when, in fact, all phenomena are radically incompatible and, most of the time, aporias and assumptions gloss over gulfs and ruptures of difference. In the notion of fusion of horizons, there is indeed a tendency to ignore heterogeneities and abysses. Hermeneutics responds with the primacy of dialogue. Interpretation must draw on both sameness and difference, both radical incompatibility and radical connectivity. Interpretation involves an unending interplay between sameness and difference in the unavoidable participation of the one and the many.

Hermeneutics and Action Research

Hermeneutics is always at work in action research, as it helps us see the binding of understanding and action. The practical application of knowledge is inherent in the very understanding of something. Practical

application is not an external, after the fact, use of understanding that is somehow independent of it. All understanding is practical; all understanding is action.

Hermeneutics agrees with action research on the importance of reflexivity in inquiry. It observes that the texts we most need to understand, in one way or another, are our own narratives. A hermeneutic perspective illuminates the play between researchers' questions to and from the world and their narrative of themselves. Their movement from the horizons into encounters and on to their new horizons gives weight to their impulse to explore, learn and co-create with others.

In stressing the centrality of encounter, hermeneutics justifies action research as a form of inquiry into struggles between people and into struggles for human flourishing and consequence. Hermeneutics highlights the insistent and never-ceasing questioning of things, and the never-ending possibilities of human conversation in bringing human beings together.

HETEROGLOSSIA

Heteroglossia means different ‘speech-ness’ or differentiated speech. A given language is not unitary but stratified; heteroglossia is a mix of languages and world views. The idea of heteroglossia is associated with the Russian theorist Mikhail Bakhtin (1895–1975), who saw everyday speech as a conglomerate of ‘sub-languages’, always used from a particular perspective and context and directed towards another. This draws attention to how we hear and speak.

Heteroglossia describes the stratification of language into different genres, dialects, generations or sociolects based on age group, gender, socio-grouping, discipline or profession and so on. There are languages that are tendentious and those that represent the voices of authorities, various circles and particular fashions. These different languages are appropriated in everyday speech.

Each stratification as a language within languages is historical, contextual and continually evolving. People do not remain within a given genre or other stratification. Rather, they are continually borrowing from different stratifications, each influencing the other. A group of professionals from a given discipline with their own particular jargon, for example, lawyers, engineers or doctors, will have their own technical language stratification. However, this is used in the context of everyday speech, which is made up of multiple stratifications. A particular professional or technical language mingles with everyday speech-ness so that it is not spoken as a separate entity but, rather, coalesces with other languages. Thus, professional jargon is itself influenced by values and norms across everyday languages.

These languages are socially unequal and therefore hierarchical. Each language has its own strategic intent, values and meaning. In heteroglossia, words or utterances are never neutral; their meanings are always context driven. Context in this sense refers not just to the speaker and the words used but also extends to the wider, more diffuse environment, for example, day of the week or time of day. Context in this wide sense colours the intended and created meanings of words.

Language is also ideological in the sense of advancing ideas. Every utterance reflects a separating out of a value from the past and is directed towards the future. Every utterance responds to that which was uttered previously and is coloured by the anticipated response. A response to an utterance comes from a myriad of possible responses reflecting particular values, weighting and an invitation to answer in that given moment.

Everyday speech is thus imbued with the speech of others as we interact with one another.

Heteroglossia and Monologism

It is conflict and inequity that distinguish the idea of heteroglossia from that of polyphony. Polyphony refers to multiple voices without reference to the nature of their interrelationship. In contrast, in heteroglossia, national languages and their subsets are imbued with historical and social conflict. Thus, from a Bakhtinian lens, language stratifications embody the conflict among social forces that results in particular representations and authoritative discourses. Everyday speech reflects conflicting social forces.

Bakhtinian scholars highlight the ethical undertones of his work; Bakhtin viewed heteroglossia as ethically superior to the notion of a singular authoritative language (monologic). Language that is stratified may become monologized by the emergence and dominance of a single authoritative voice.

In heteroglossia, there is a dialogic interaction in which dominant languages higher in the hierarchy will try to maintain their position, while those lower down the hierarchical chain will try to negotiate around or avoid control by the other. Within any utterance, there are stratifying forces that produce a complex mix of the appropriated speech of others to produce a view of the world. Centripetal forces seek to gravitate towards a dominant language and the status quo towards a unified authoritative view. Centrifugal forces seek to decentralize, differentiate from and pull away from a unified view. Tension is the central characteristic of heteroglossia. At the heart of this struggle are power and its distribution among the different views represented in languages and their subsets. The conflict between centripetal or official and centrifugal or unofficial discourses within a national language is one in which the dominant or the official seek not to destroy but rather to dominate or monologize.

Heteroglossia and Action Research

Where action research scholars place an emphasis on participation, power and voice, heteroglossia expands the debate by questioning the term *voice* in any singular or overarching sense, for example, representing the voice of an individual or stakeholder group. Such questioning can follow two interrelated strands:

1. Shifting the focus on participation to narratives
2. Attending to the multi-voiced language of our individual speech and inherent conflicts with the espoused values underpinning our action research efforts

Participation

Participation in action research is described by Peter Reason and others as being both epistemological and political. In the epistemological sense, participation is a joint meaning-making process. This requires full engagement with different experiences, views and understandings of the world. In the political sense, action research recognizes the ability and the right of individuals to have a say in how knowledge is generated about them and the decisions that might affect them. Participation in action research recognizes meaning making in everyday practice as an intensely political affair.

In heteroglossia terms, a joint meaning-making process which ensures that participants have a say in all aspects of the process may obfuscate the privileging of some narratives that reflect particular world views over others. Participation turns to our language stratifications and the forces around them that are implicit in our everyday speech even as we seek to give voice to participants. Forces may reflect institutional and professional values and norms that colour the context of our utterances and, importantly, how they are interpreted by 'recipients'. Concerns shift from who is speaking to also scrutinizing the nature of our speech and the different voices therein.

Multi-Voiced Speech

Attention to heteroglossia in a particular environment expands the focus of voice to the multi-vocal nature that is implicit in our speech. This opens up a focus on how people hear others and how they listen to their own utterances, and the narratives that are privileged therein. The temporal, spatial and social contexts of their utterances become important in how they interpret their interactions with both the action research process and the participant. By acknowledging heteroglossia in their interactions, they enter into a dialogic relationship in which dialogue relates to the context of words spoken and the forces behind them. Heteroglossia, thus, offers action researchers a way of conversing with the subtle competing values that lie below the surface of their speech.

HEUTAGOGY

The term *heutagogy* was first coined by Stewart Hase and Chris Kenyon in 2000 as an extension to andragogy and means self-determined learning. Its foundations are constructivism and humanism, along with capability, open-systems thinking and complexity theory. It came about because of the founders' dissatisfaction with education and training systems based on antiquated concepts of learning and teaching principles. It is clear that we are in a new age of learning emancipation, where there is instant access to copious information and easy communication with others. No longer is the guru standing at the head of the classroom necessary in order to learn. Since 2000, there have been a large number of papers written both by the originators of the concept and by educators around the globe. As discussed later, action research has both theoretical and practical ties with the concept.

Heutagogy is based on the fundamental assumption that people are capable learners and they learn when they are ready and not when the teacher thinks they should be. Thus, the focus is on learner-centred learning, where the learner has increased control over the content and the process of learning. This is compared with teacher-centred learning, where control of task and content is completely in the hands of the teacher. According to heutagogy, children are excellent learners before they go to school, where their skills are hampered by a system that relies heavily on the teacher, the curriculum and assessment rather than the experience of the learner. Heutagogy is concerned with great learning rather than good teaching.

Recent advances in neuroscience have increased our understanding of how the brain works and how people learn. On the basis of this, heutagogy seeks to redefine what we mean by learning. The most common definitions of learning have to do with knowing or knowledge acquisition, and the psychological definition has for a long time been that learning involves a change in behaviour.

Instead, heutagogy differentiates between acquiring knowledge and skills, which are otherwise known as competencies, and deeper learning. People often acquire knowledge or a skill that has no value beyond itself. For example, a person may repeat a skill in

familiar circumstances, but the real test is when the competence is required in an unfamiliar situation (what John Stephenson and colleagues call capability). However, sometimes and for reasons that are not altogether clear, we have an experience that leads to all sorts of new insights that clearly involve an interaction of many networks that became activated. In this case, one is able to use one's skills in a new, challenging situation, or new knowledge results in a new theory or way of seeing the world.

What is important here from a heutagogical point of view is that this may lead to a whole new set of questions, behaviours and needs on the part of the learner that go beyond the set curricula, lesson plan or workshop programme. The teacher will not be aware of this change in the motivation of the learner, this shift in interest. Thus, the curriculum, assessment and learning process need to be flexible in order to cope with the changing state of the learner.

Heutagogy in Relation to Action Research

Action research provides a methodology and a set of techniques that are well suited to heutagogical principles and comes from a similar philosophical stable. As an emergent process, action research provides an opportunity for participants to reflect on what they have learnt following the acquisition of new data and to rethink what needs to be done next. The identification of new questions and new ways of seeing the world is central to action research, as it is in heutagogy.

Action research also provides an opportunity to explore the new learning, usually in a participatory process. This is particularly valuable in dealing with complex situations. However, given that researching new ideas is so easy with the massive resource that is the Internet, other people do not necessarily have to be involved. There is also ample opportunity for participants to explore particular areas of interest.

Thus, action research can be used as a teaching method at any level of education and training as an alternative to teacher-centric approaches. The teacher becomes a facilitator of the process rather than guru, and learning is placed more in the hands of the learners.

Heutagogy claims that children are already competent learners before they go to school, where the capacity is dulled by inflexible curricula and the teacher-centric process. Action research provides a process to rekindle this ability to learn and for people to become effective lifelong learners and better reflective thinkers.

HIGHER EDUCATION

Action research has long been engaged with the educational system at all levels: K–12, higher education and adult education, but the higher education dimension of action research is its least developed component. Action research is inherently contrary to the Fordist organization of higher education because that system is inimical to studying and solving complex real-world problems in their multifaceted complexity. Paradoxically, becoming an action researcher generally requires university training, and universities are reservoirs of key forms of expertise that can and must be used to solve humanity's growing global problems. Thus, higher education reforms to promote action research are necessary. This entry examines the current status of action research within higher education, discusses the ways in which the existing Fordist model of higher education works against both action research and the ability of higher education to effect positive social change and, finally, proposes a new structure for higher education based on an action research model as a more

engaged and democratic alternative to the current system of higher education.

Learning Action Research

Action research courses are taught at various university venues from anthropology, sociology, planning, education, nutrition and programme evaluation units but not as a fully realized curriculum or degree programme. Generally, individual courses are offered in unlinked departments, and students thus must find the courses and meet other like-minded students to network with in pursuit of their goals.

There are a few action research Ph.D. programmes worldwide. The Ph.D. programme in Industrial Economics and Technology Management at the Norwegian University of Science and Technology (NTNU) permits individualized courses of study in action research under the direction of Morten Levin. In Norway, the Norwegian University of Science and Technology and in Australia, Southern Cross University, Deakin University and Curtin have all had action research curricula or formal programmes from time to time. Previously, an action research centre was run by Peter Reason at the University of Bath, but it ended with his retirement, and a new programme has recently been started at the University of Bristol by Patricia Gaya. The University of Cincinnati in the USA currently offers a doctoral concentration in educational and community-based action research within its educational studies programme. Despite these efforts, the lack of a clear undergraduate curriculum and the instability and short lifespan of action research postgraduate programmes show that higher education is generally a hostile environment for such work. Most students enter Ph.D. programmes in conventional fields such as anthropology, education, sociology or planning and then get part of their training in action research from individual faculty at their chosen university while they receive most of their training within conventional disciplinary structures. Faculty in action research often serve as second or third members of master's and Ph.D. committees, providing action research perspectives on work within the student's main discipline.

If students want to conduct an action research project for their thesis or dissertation, they face additional difficulties. Action research projects depend on the needs, wants and capacities of non-academic stakeholders. Developing and maintaining strong relationships with a stakeholder group while a full-time student on a university campus requires organizational ingenuity. Funding is often problematic since action research projects do not fit the guidelines for many of the typical research funders in graduate education. And getting permission from Human Subjects Review

Boards for action research projects often requires complex argumentation.

Writing up the results of action research projects in theses and dissertations presents additional issues. Conventional academic writing is not suited to action research projects. Rather than formal thesis statements, literature reviews and so on, action research writing is more ethnographic, narrative and contextual in developing ideas and arguments. The process of doing the research often is central to the narrative and necessary to the credibility of the results. But doing this runs afoul of the positivistic canon of thesis writing and subsequent publication. These issues, fortunately, are discussed by Kathryn Herr and Gary Anderson in *The Action Research Dissertation* (2005)—a book on doing a dissertation in action research and an invaluable guidebook for action research thesis writers.

Action researchers also face intellectual property issues. Action research is the product of a collaborative learning group. The intellectual property created does not belong unilaterally to the professional researcher. In writing about the project, the researcher often speaks for others and feels compelled to check with those 'others' and have them review and approve the results of the writing. In some cases, the non-academic collaborators have written their own reactions to the thesis or dissertation, and in one case, namely, Michael Reynolds' dissertation on science education at Cornell University, the authorship of these writings was identified and included in the dissertation, and the co-authors participated in the defence.

A major venue for undergraduate training in action research is what is variously called service learning or civic engagement programmes, pioneered by Timothy Stanton, Dwight Giles and Nadine Cruz. A small proportion of undergraduate students seek service-learning placements that involve working in community organizations and service agencies. Often, these are internships and rarely involve much faculty oversight and advising to integrate the work into the students' curriculum. One exception is the work of Nimat Hafez Barazangi. Most academic institutions treat these as 'co-curricular' activities and as non-academic work, thereby undercutting the relationship between action and reflection central to action research.

Despite the above difficulties, scores of action researchers have been trained in higher education over the years, and more will be trained in the future. A modest literature on these processes now exists.

Action Research Within Higher Education Institutions

Public higher education, which, given public funding, might have been expected to support action research

projects for the benefit of the public, has generally failed to do so. Instead of engaging the stakeholders in collaborative problem identification and problem-solving, public universities adopted the academic expert and consultant model dominant at elite private institutions. While a modest number of action research projects have taken place in such institutions, focused mainly on community development, youth development, support for public schools, small-business development and so on, it is nowhere a dominant focus. Examples of this kind of action research work can be found in the writings of Scott Peters, but they are clearly minority practices.

Action Research and Higher Education Reform

Truly rare is the use of action research in projects to transform higher education institutions and higher education policymaking and implementation. A few dissertation projects have addressed this, such as those of Betsy Crane, Reynolds and Rebecca Moore, and one university was founded by using an action research process directed by Ogüz Babürüglü. These prove that such interventions are possible. But most of the publications on this subject are by Greenwood and Levin, who are repeatedly invited to provide the only chapter on higher education and action research in the last three editions of the *Handbook of Qualitative Research* and the two editions of the *Handbook of Action Research*.

Given the state of crisis in higher education, what should disturb action researchers is that they have been incapable of launching sustainable reforms to reorient universities using action research. Instead, if anything, the 'new public management' has succeeded in recasting students and the public and private sectors as fee-for-service customers. Supporting that, they impose a narrow form of accountability on higher education, counting publications in variously ranked journals, the citations to those publications, the funds in research grants attracted, the students employed after graduation and the average salaries of those students.

What are better ways of organizing higher education that do not reduce students to customers, teachers to fee-for-service trainers, researchers to grant-getting entrepreneurs and academic administrators to mini-CEOs of what still are mainly not-for-profit institutions? Proposals that go beyond calling for the return of some mythical good old days are few.

The industrial democracy movement in Scandinavia provided a promising starting point for university reform there. Focused on work organization and the reorganization of work along democratic and solidarity lines, action researchers helped change working conditions in factories, social service agencies, health-care

institutions and so on. But these successes in organizational change have not been applied to the structures of higher education themselves, which remain largely as they were before this work began.

The conventional structures of most higher education institutions are the academic expression of Fordist organizational structures that the industrial democracy movement worked to alter, a point made by Christopher Newfield as well as Tony Becher and Paul Trowler. Nearly all higher education institutions are divided into sub-disciplines—disciplines which are departments and colleges and so on—and there is a clear division between the statuses of students, faculty, support staff and administrators. In this version of higher education, the disciplines together make a university in which all subjects are known and can be taught by experts. How to integrate this knowledge in actionable frameworks for societal benefit is rarely addressed. Students are given curricular requirements to meet, and after 4 years of moving from department to department taking courses from faculty, who are neither generally aware of nor particularly interested in each other, they are said to be 'educated' and given a degree.

Faculty are mainly rewarded for demonstrating expertise in their own particular subcategory of work, vis-à-vis not other colleagues at the institution but other colleagues in their disciplines, nationally and internationally. There are few incentives for them to co-operate with each other, particularly in the social sciences and humanities. Ranking and career success are based on extra-campus recognition.

Administrators are paid increasingly well for running these institutions in what many faculty and students falsely believe is the 'corporate' style. They are increasingly becoming administrative careerists whose trajectories are a series of upward moves to more senior positions and more highly ranked institutions. They are portrayed well ethnographically by Gaye Tuchman and Benjamin Ginsburg.

From the point of view of action research, this is wrong-headed. Since the world is made up of complex, multidimensional, dynamic systems that struggle to adapt to constantly changing conditions, to study these phenomena and to pretend to act on them by artificially dividing them up into spheres of academic disciplinary commodity and expertise production destroys any possibility of understanding or acting on them.

In various writings, Morten Levin and this author have articulated some of the reasons behind these organizational pathologies. One key cause is that action research requires a process based on iterative cycles of research, reflection and action in collaboration with non-academic stakeholders. To the extent that Fordist administrators want to control the boundaries of their institutions and academic actors enjoy their

freedom and isolation, both groups oppose free and fluid interchange over the boundaries of the university and society. They oppose interactions across departmental boundaries for similar reasons.

Faculty members and students brought up in this world have come to see themselves as experts and proto-experts climbing professional ladders. They react with fear and rejection to the idea that the ladders they are climbing are fundamentally meaningless to society at large. So they too enforce the narrow Fordist organizational structure.

Another reinforcing mechanism, visible from the vantage point of action research, is the intellectual property regime. By dividing knowledge into separate bits of expertise and rewarding individuals for creating and transmitting these bits, this model conceives knowledge as a commodity to be created by a producer and sold to a consumer (e.g. student, corporation and government) for a price. In some cases, the price is extracted in return for teaching.

Since a key premise of action research is that knowledge is socially constructed in learning arenas in which many collaborate and the condition for knowledge generation is the free and open exchange of ideas and information, action research views the current intellectual property regime of universities as completely false and extractive. By not recognizing and promoting the social basis of knowledge creation, Fordist universities actually curtail the development and transmission of knowledge.

And finally, political and economic powerholders view any kind of activist research, including action research, as a threat to the exploitative arrangements that support their dominant social, economic and political positions.

This brings us to a central contradiction in the current organizational environment of higher education worldwide. Increasingly, with the attempted marketization of all public sector institutions, everything public, including public higher education, has marginalized dimensions of higher education that do not lead directly to a productive, well-paid job. Most of the policymakers and administrators in higher education have joined a worldwide movement to make higher education institutions 'transparent', 'accountable', 'efficient' and employment relevant. These accountability schemes take the current Fordist structures of higher education for granted. Thus, they impose numerical competitions and prizes on individual students, faculty, departments, colleges and universities that treat each of their activities as a quantifiable one to be measured by experts. These quantified scores provide the basis for a pseudo-objective system of ranking that institutions of higher education struggle to rise in.

The effects of these systems are widely known already, as the British research on the subject by David Rhind showed. They result in narrower research and teaching, less collaborative work, shorter time horizons for research projects, more narrow publications to maximize the number of articles emerging from each project and so on. They cause a race to the bottom in quality and scope of research and punish anyone for doing more abstract, blue-sky, long-term or multidisciplinary work.

Action research, on the other hand, proceeds on the assumption that a great deal of relevant knowledge already exists but is not available for action until all the relevant stakeholders are engaged in a collaborative process of description, analysis and action design. All these different stakeholders have different criteria for what will be a valuable intervention and outcome, and given their relative positions, they are able to judge first-hand the effects of actions designed by an action research collaborative group. In action research, the organization of the collaborative learning community seeks to be coextensive with the scope and complexity of the problems under study.

Considering the kinds of problems that currently are major priorities globally—climate change, the mal-distribution of wealth, hunger, preventable illness, environmental destruction, sustainability and renewable energy—failure is guaranteed by trying to cope with such issues through a Fordist system. Action researchers believe that universities can be organized and reorganized to match these problems better and to begin a more effective process of providing actionable research and strategies to deal with them. But doing so would mean significant reorganization of the ways universities do business and of the ways they are held to account by policymakers and politicians and lots of internal shifts in power positions.

In this brief entry, it is not possible to develop a full alternative design for universities, but here is a sketch. The design conditions are as follows: High levels of expertise available at universities can be valuable, expertise must be deployed in collaborative learning communities including academics and non-academic stakeholders and the configuration of the knowledge and stakeholders must match the complex contours of the major systems problems the world faces.

Starting with an inventory of key large-scale system problems faced in the world, universities could configure themselves as matrix organizations with a variety of teams of academic and non-academic stakeholders integrated into collaborative learning communities around specific problems. These communities, seconded from disciplinary departments, would set the goals, conduct the research, design the actions and collaboratively examine the results and publish

them. Once such a team had accomplished the major work that energized the initiative in the first place, the faculty would return to their disciplinary departments awaiting the next opportunities.

Central leadership in such an organization would no longer be the distant authoritarian managers of the Fordist system. Leaders would be co-ordinators and facilitators of the work of the teams and would liaison with the external world in search of important problems for the action research teams to address and funding to support them. Faculty hiring and promotions would be guided and evaluated in view of their contributions to these problem-solving collaborative learning communities and not merely for their individualistic academic commodity production.

Student training would be as much by apprenticeship in these collaborative learning communities as by passive education in classroom settings. Students would learn to conduct meaningful research by participating with multidisciplinary teams of researchers and other stakeholders and would be, in effect, apprentices to both the faculty and the teams.

Funding and political support for these action research-centred institutions would arise from the demonstrated importance of their work and their ability to show clear results in the context of the application of their knowledge to solving real-world problems.

Could such institutions exist? Not until action researchers take a more focused and organized stance in opposition to the current Fordist model of higher education.

HIGHLANDER FOLK SCHOOL

See Highlander Research and Education Center

HIGHLANDER RESEARCH AND EDUCATION CENTER

The Highlander Research and Education Center, located in New Market, Tennessee, in the southern Appalachian Mountains, serves grass-roots social change movements in the southern and Appalachian regions of the USA. Founded in 1932, in Summerfield, Grundy County, as Highlander Folk School during the Great Depression, it became an educational centre for labour organizing in the 1930s. Racial segregation was legal in all the southern states, and Highlander, as an integrated facility, became a centre for the Civil Rights Movement in the 1940s and 1950s. Threatened by Highlander's work for civil rights, the state of Tennessee closed the centre in 1961 and revoked the charter, and Highlander lost the Grundy County site. Highlander leaders quickly re-chartered as Highlander Research and Education Center, and educational efforts continued, first in Knoxville, Tennessee, and then, beginning in 1971, at the workshop centre in New Market, Tennessee. In the 1960s and 1970s, Highlander was involved with groups related to coal mining and poverty issues in central Appalachia. Since the 1980s, education

programmes have focused on economic justice, human rights, environmental sustainability and democratic governance. Research for organizing efforts has always been a part of Highlander's work but developed into a more overt strategy with community economic and environmental efforts in the late 1970s and 1980s. This entry covers the history of the Highlander Center, information about Highlander's educational process and the development of Participatory Action Research as part of that process, with examples of how those processes supported organizing efforts in the southern and Appalachian regions of the USA.

Education at the Highlander Center

Highlander developed an education philosophy and practice to support participants from marginalized communities who share and analyze their experiences in order to bring about social change. Myles Horton, one of Highlander's founders, was very influential in the development of Highlander's educational methods (which he called 'education for social change') until his death in 1990. Workshops develop relationships through which participants find commonalities and differences, analyze their situations and explore new ideas for strategies in order to return home stronger and better prepared to address issues and build long-lasting efforts with other groups. Highlander staff also visit and work in local communities and with larger networks and organizing efforts. Highlander supports people and groups to build their capacities to strengthen organizing, building networks and, hopefully, movements. Participants eat together, share sleeping space and interact also during breaks, campfires and free time. These times are as important as the planned workshop meetings for building connections.

Out of Highlander's workshops, new organizations, initiatives and movements sometimes form. The Citizenship School programme, led by Septima Clark in the 1950s, began in the African American community on John's Island, South Carolina, and became an outstanding programme that spread throughout the South. John's Island is one of the Sea Islands off the southern coast of the USA, where families of former slaves remained after the Civil War. Esau Jenkins, a leader from John's Island, attended a 1954 workshop on the United Nations at Highlander. During the workshop, Jenkins shared his experience that the problem they had was barriers to voting for African Americans. There was a literacy test for voter registration in South Carolina that required people to be able to read a section of the state constitution.

Over the next 2 years, Clark, a former teacher from Charleston, South Carolina, Highlander staff and Jenkins initiated efforts to deal with the situation. Bernice

Robinson became the first teacher. She developed lessons with John's Island residents around their need for voter registration and also other practical needs such as being able to fill out catalogue order forms. People from other Sea Islands began requesting similar classes. Clark and Robinson developed the curriculum out of the needs and experiences of local residents in the Sea Islands of South Carolina and went on to train teachers from across the South. By 1961, the Southern Christian Leadership Conference, a Civil Rights Movement organized by Martin Luther King Jr., took on this programme, continuing to train teachers to conduct citizenship schools. This programme laid a foundation that would help build political participation in many communities during the Civil Rights Movement in the 1960s.

Culture has been a key ingredient of Highlander's educational work. Incorporating music, drama, art and other forms of culture to strengthen organizing encourages people and communities to recognize and build upon cultural strengths. Zilphia Johnson Horton, who came to Highlander in 1935, collected songs written by workers, created song sheets and taught people to be song leaders, who then took the songs back to the labour union struggles. Other cultural staff built on her legacy to link cultural work to organizing and campaigns. Attention to language as a communication and cultural issue at Highlander came out of work with new immigrant communities in the South and Appalachia in the 1990s. Highlander held bilingual workshops to ensure democratic communication across language and developed educational materials to train interpreters, translators and organizations in the region.

As part of this educational and organizing process, access to information that informs strategy is critical and has always been part of the educational process for Highlander. As groups organize to address issues, they must find out information to help them determine the best strategy. They share vital information during and after Highlander workshops. An emerging community environmental health focus developed in the late 1970s, as well as an Appalachian effort to document land ownership, which created a need for more technical research and resulted in an enhanced Participatory Action Research programme at Highlander.

Participatory Action Research at Highlander Center

Working in Appalachia with communities developing health-care clinics, Highlander encountered problems of occupational and environmental health issues in the region. Communities needing to know why cancer rates were high or why miners and millworkers had breathing problems led them to look at environmental

and workplace conditions. Black lung from coal mines, brown lung from textile mills, toxic waste creation and disposal and air and water pollution from chemical plants all became major issues in the region. The need for research on health, chemicals, laws and regulations, permitting processes and corporate research—areas where ‘experts’ and ‘academics’ were seen as essential—became more critical for organizing. Practically, the Highlander research programme was not able to meet all the demands for research from community groups, so teaching people how to do their own research was needed.

This increased need for technical information led Helen Lewis, John Gaventa and Juliet Merrifield to develop an enhanced participatory research programme at Highlander. The Highlander library was expanded as a research library, and Participatory Action Research workshops and projects provided ways to push and test this work, always connecting to issues that were being addressed in the region. Education, organizing and research were intertwined with the goal of changing the situations of marginalized communities.

Over the years, Participatory Action Research has taken many forms. Highlander staff began to see their role as helping to train community researchers instead of being the researchers; the other prong of this effort was pushing ‘experts’ and academics to be aware of the knowledge and capabilities that community members bring to their fields and to work in respectful relationships to determine needs and support community participation in the creation and control of information. Merrifield laid out the importance of issues of control, ownership, use and accountability in ‘Putting Scientists in Their Place’ (1993).

Examples of Highlander Participatory Action Research Work

Appalachian Land Ownership Study

From 1979 to 1981, the Land Ownership Task Force of the Appalachian Alliance undertook a participatory research study to document land and mineral ownership in six states in Appalachia. Over 60 researchers co-ordinated by member groups gathered data from property records in 80 counties across six states, with Highlander Center and the Appalachian Center at Appalachia State University serving as institutional bases. After a massive compilation effort, these reports documented patterns of concentrated corporate and absentee ownership of land and minerals, such as 53 per cent of the land being held by 1 per cent of the owners, along with the low levels or lack of taxation of these resources, making links to the economic and social conditions of the counties. The report was

funded by the Appalachian Regional Commission, but this agency refused to publish the findings, so the Appalachian Alliance printed the results. Groups in the region used the results of the study in organizing efforts and influenced academics who desired to join their knowledge to community efforts.

The Community Environmental Health Programme

In the late 1970s, a growing, community-based environmental movement emerged out of community efforts to control toxic industries, resource development and waste disposal facilities that were affecting their homes and health, both in the South and in Appalachia.

In 1977, Highlander started working with a group of residents in Kingsport, Tennessee, to document the air and water pollution from the Eastman Kodak plant there and its potential health effects. Following from that work, Lewis secured funding from the National Science Foundation for the Science for the People project. One of the forums was at Bumpass Cove, where landfill owners were taking hazardous waste into the site and local residents began noticing health problems. When the river flooded, washing out toxic waste barrels, residents blocked the road to stop the trucks bringing in materials. They formed a group, the Bumpass Cove Concerned Citizens, and gathered files from the Tennessee Department of Health. Members brought stacks of information from the permitting files to Highlander, and the staff provided assistance and research manuals to help them determine what chemicals were being brought in and what health effects the chemicals would cause.

From the late 1980s until the late 1990s, the ability for communities to research environmental issues and share that information across communities empowered a wave of organizations fighting to stop local pollution, linking them to more technical resources available. Intermediaries like Highlander Center, the National Toxics Campaign and Citizens Clearinghouse for Hazardous Waste provided support, and environmental justice networks growing out of the People of Color Environmental Summit of 1991 provided critical technical resources to support this movement, including workshops, meeting opportunities and field support. Highlander held a series of workshops from 1989 into the late 1990s, which brought together hundreds of community and union leaders and members to share information and strategies for confronting new and existing toxic production and disposal facilities. Education, research and organizing were all essential and intertwined in these efforts.

The growing environmental justice movement also linked globally with peoples’ struggles around the

world. In the 1980s, Gaventa and Merrifield met with and documented the shared struggles of communities living next to Union Carbide facilities in Bhopal, India; Institute, West Virginia; and Oak Ridge, Tennessee. Gaventa and Merrifield travelled to all these communities and made a video to send to Bhopal and produced a joint report on Union Carbide with activists in India.

For the UN Conference on Sustainable Development in 1992, Highlander's Community Environmental Health Program gathered stories written by groups fighting toxic and environmental problems across the USA and compiled these into a report, which was distributed by a delegation from Highlander to participants from other countries at the Rio Conference.

Economic Education and Globalization Research

The 1980s saw a wave of deindustrialization as factories moved to other countries for lower wages, along with growing mechanization in mines and farms. Many struggling areas of the southern and Appalachian region were seeing new economic challenges. The Highlander Economics Education Project began in 1985 to develop an economic development curriculum for rural communities. This curriculum, carried out with community groups in Dungannon and Ivanhoe, Virginia, and Jellico, Tennessee, emphasized local knowledge and research on the local economies in order to develop strategies to strengthen them.

In 1989, Highlander supported a new community labour coalition, the Tennessee Industrial Renewal Network, to research and organize around deindustrialization in Tennessee.

Factory workers who were part of the Tennessee Industrial Renewal Network, and who had themselves dealt with factory closings, organized trainings and worked with Highlander staff and other people to create a handbook for displaced workers. Exchanges between factory workers from Tennessee and those in the maquiladora production zone of Mexico were organized into slide shows, presentations and videos to educate people in Tennessee about the North American Free Trade Agreement and the effect of this economic globalization on communities in the USA and Mexico.

A rapidly growing immigrant population in the South was a new reality in the 1990s, with the largest numbers of new immigrants coming from Mexico as a result of the North American Free Trade Agreement and the resulting economic devastation in that country. Educational efforts at Highlander were directed at supporting new immigrants largely from Mexico and Latin America, while also linking these communities to Highlander's traditional constituencies of African American and marginalized White communities. As new issues emerged around immigrant rights, Highlander connected

research with educational and organizing needs at workshops and in new coalitional efforts.

Highlander continues to help communities find information, increasingly including information in multiple languages. With the Internet, the need for a research library has decreased, but assisting groups in strategically determining research needs and where to find information, and how to gauge the source and accuracy, is a critical function. Navigating vast realms of information, not a lack of information, is the challenge. Information literacy, the need to help people learn more about strategies and resources for finding and using research, is critical to helping them navigate the constantly changing information world.

HIV PREVENTION AND SUPPORT

The global HIV (human immunodeficiency virus) response has increasingly become intertwined with

action research. Due to many unique historical factors, the global HIV movement is rooted in social justice, human rights and activist ethics. This has resulted in global health policies that advocate for the active participation and inclusion of people living with HIV, and those who are most affected, in research and policy development. As a result, action research has been widely employed to support the production of knowledge that is consciously informed and/or led by the lived experiences of those most affected by the virus. The varied methodologies within action research aim to ensure collaborative and participatory processes. These inclusive practices have become a vital component of HIV intervention development and evaluation, which have led directly to informing policy and calls for social change to mitigate the impacts of HIV around the world.

HIV is the virus that leads to AIDS (acquired immunodeficiency syndrome). The epidemic of HIV and AIDS is one of the largest global health crises that the world has ever known. To date, more than 30 million people have died from AIDS-related causes. At the end of 2010, there were 34 million people living with HIV around the world.

The spread of HIV follows paths of inequities and is exacerbated by social disparities. People who have long been marginalized in society often face the greatest impacts of HIV. The populations most affected by the global epidemic include women, young people, gay men, people of colour, people who use illicit drugs, people in prisons, sex workers, transgender people and people living on low incomes.

To adequately address the devastating impacts of HIV, the response aims to both prevent its further spread and treat, support and care for the people who have acquired the virus. In the past, these varied approaches could be seen independently or in tension with one another. But today, prevention, treatment, care and support interventions are primarily viewed as mutually complementary. As such, HIV prevention itself is defined as involving a combination of diverse interventions aimed at curbing infections, including those that are *behavioural* (promoting condom use and other harm reduction interventions), *biomedical* (increasing access to testing and antiretroviral treatments) and *structural* (facilitating supportive policy and legal environments and addressing economic inequity and cultural and social factors that lead to vulnerabilities for people affected by and living with HIV and AIDS).

HIV treatment involves ensuring consistent access, quantity and quality of antiretroviral therapies for people living with HIV and the treatment of opportunistic infections that arise from living with a compromised immune system.

HIV care and support often involve programming and interventions such as psychosocial and mental health services, nursing, home care, information and educational supports, training and capacity building.

Those first to respond to the crisis in the 1980s were a diverse range of HIV-infected people, their friends and activists in gay, lesbian, bisexual and transgender communities in North America. In an environment of state inaction towards the devastating crisis, there was a lack of government or institutional recognition, support and funding. Despite this, a strong and vibrant activist and community self-care response evolved to counter the institutional AIDS stigma, homophobia and racism towards those most affected by the emerging virus. During this time, a wide range of community organizations evolved to respond to the crisis, and due to intense social movement organizing and activist pressure, some political leaders began to acknowledge their responsibility to respond.

Resulting from the enormity of the impact of HIV, today the socially organized response to this global epidemic is highly unique and consists of diverse actors from many sectors of society. While lack of political will to respond, stigma and discrimination still exist, the global HIV response today has expanded to comprise people living with HIV, activists, community and non-governmental organizations, multilateral and international funding institutions, governments, the private sector, doctors, scientists and researchers as well as public figures.

Due to its scale, complexity and impact, and the resulting resources and political commitment needed to attend to it, the HIV epidemic, and the response to it, has been noted as needing exceptional attention. This is what is called *HIV exceptionalism*. The exceptionalism of HIV has resulted in specified funding bodies; global, regional and country-specific strategic response plans and a massive global mobilization of resources to address the health crisis. Despite calls for an exceptional response from activists and intuitions, activists complain that the lack of political accountability from government leaders continues to result in many not being able to access the necessary drugs to treat the virus.

As a result of the widespread activist force that drives the HIV movement, responses to the epidemic are often now framed through a human rights lens. In the early days of the HIV epidemic, people living with HIV were often excluded from major policymaking forums, events and conferences focused on the response, as these platforms were often exclusive to members of the medical establishment and governments. Activist pressure calling for the human right to participation and inclusion led to the development of ethical principles intended to underpin the HIV responses.

The call for active and meaningful participation of people living with HIV in decision-making that would affect their lives and support the development of appropriate HIV responses was recognized in 1983 with the Denver Principles. These principles called for people with HIV to be recognized as people with expertise, who could contribute to the response, rather than being viewed as passive patients. In 1994, governments recognized these calls with the Paris Declaration. This declaration signed by 42 governments formalized and declared the *Greater Involvement of People Living with or Affected by HIV/AIDS* as a critical ethical approach to ensure effective national, regional and international responses to the epidemic. Today, this principle of participation has become known as the Greater Involvement of People Living with HIV and AIDS, or GIPA.

There are now numerous international treaties and commitments that acknowledge and support the involvement of those living with and affected by HIV, including the 2001 United Nations General Assembly Special Session on HIV/AIDS Declaration of Commitment and the United Nations High Level Meeting Political Declarations. Through these declarations, participation of people living with HIV is intended to address and inform the complexity of how the epidemic manifests differently in different contexts and communities. These documents also recognize that to be successful, all of the varied prevention, treatment, care and support interventions must be tailored to specific communities and must be culturally relevant, acceptable and accessible to the wide range of diverse people who are affected by HIV, which is only a viable undertaking when these communities are actively engaged.

Outside of government declarations, the GIPA has been integrated into government national AIDS plans, organizational policies in NGOs (non-governmental organizations) and research guidance documents. In some countries, HIV and health-specific action research networks, practitioners and institutions have included GIPA as an ethical principle that is to be operationalized in research protocols. This can be undertaken in a number of diverse and creative ways, including the creation of community advisory boards to oversee and inform research projects and through training people living with and affected by HIV to develop research expertise. In some countries, there are also community-based Ethics Review Boards for HIV-specific action research, which also include members who are living with and affected by HIV.

Within these approaches, it is recognized that practitioners of participatory methodologies, which promote collaboration with people from a variety of disparate backgrounds—such as action research—must seek to ensure reflexivity to continually address

and acknowledge how power is operating during the research practice. As many people living with HIV have faced social marginalization due to their lived experiences, addressing power within action research on HIV can help ensure that these people are not exploited, used instrumentally or further marginalized.

Action research itself has become increasingly recognized as a way to produce knowledge that can be owned by communities affected by HIV to help address their own needs. It is also well situated as a methodology to support the development of knowledge to address complex structural barriers and access disparities that the HIV movement seeks to change. Many community-based HIV organizations have now integrated forms of action research into their ongoing work. The development of prevention, treatment, care and support interventions regularly begins with an action research project developed collaboratively through community-based organizations and research institutions.

HORTON, MYLES

Myles Horton was the co-founder of the Highlander Folk School in Summerfield, Tennessee, in 1932. It was a school to educate adults for social and political change in the South. The school became deeply involved in the major social movements of the region: labour union organizing, civil rights and Appalachian coal mining issues. Horton was the director until 1970

and an educator until his death in 1990. His educational philosophy and pedagogy were paramount in the development of Highlander's educational programme, which was based on the experiential knowledge of participants and included democratic, participatory education methods similar to what is now called action research.

Early Influences and Education

Horton developed his philosophy of education and method of operation from the social and economic situation which he had experienced. Growing up in a poor sharecropping family in Tennessee, he experienced the economic realities of the Great Depression and the exploitation of rural communities. An avid reader and inquiring student, he attended Cumberland University, a Presbyterian college in Tennessee. In college, he taught summer Bible school in the mountains. In Ozone, Tennessee, a small mountain community, he developed community discussions with the parents of the Bible school children. They discussed the problems of the communities, and he became interested in the possibilities of adult education and community participation to deal with the social and environmental problems of the region.

In college, he was active in the Young Men's Christian Association and participated in interracial conferences, and after graduation, he worked as secretary of Tennessee's Young Men's Christian Association. He continued his dream of developing a school for adults, and a congregational minister, Rev. Abram Nightingale, who had become a friend and mentor, encouraged him to learn more in order to do adult and community education. He gave him a book by Harry Ward, *On Economic Morality and the Ethic of Jesus* (1929), and urged him to go to New York to Union Theological Seminary to study with Ward. At Union, he also studied with Reinhold Niebuhr, who headed the Fellowship of Socialist Christians. Niebuhr became a lifetime friend and supported Horton's dream to develop a school in the mountains.

In New York amid the stock market crash, he saw first-hand the collapse of the industrial system, observed jobless bread lines and labour strikes and listened to the radical speeches of communists, socialists and activists of all sorts. Horton was also influenced by the New Deal programmes, populist politics (including Fabian socialists) and Karl Marx, whose work influenced him, he once said, not because of the conclusions but in his approach to understanding and analyzing society. While in New York, he also learned from the progressive educators John Dewey and George Counts. In order to further explore and develop his educational philosophy, he went to the University of Chicago to study with the sociologists Robert Park

and Lester F. Ward, and there he met Jane Addams of Hull House and learned about settlement houses.

Still seeking a model for his educational work, he was advised to visit and observe the Danish folk schools. He spent a year in Denmark and was influenced by the folk schools, where people learned from their own experiences and related their education to life problems. He also observed a number of practices which would become a part of the way Highlander operated, including peer learning, group singing, freedom from examinations and students and teachers living and working alongside one another.

The Founding of Highlander Folk School

When Horton returned from Denmark, he met Don West, a recent graduate from Vanderbilt, an activist and a social gospel preacher, who also wanted to start a school to change the South. They convinced Lillian Johnson, who had developed an education centre in Summerfield, Tennessee, to let them use the facility. In November 1932, the Highlander Folk School opened, and they were joined by a group of young men and women greatly influenced by social gospel theology, Christian socialism and the populist politics of the times. The young radicals included James Dombrowski and John Thompson, Horton's classmates from Union Theological Seminary, and Elizabeth Hawes from Brookwood Labor College. Zilphia Johnson from Arkansas joined the group in 1935 and married Horton. She added music and drama to the curriculum, and Mary Lawrence, who joined the staff in 1938, was a leader in the labour programme. Don West, the co-founder, left Highlander soon after the founding to work with unemployed workers in Georgia.

Highlander first became a school for the unemployed, striking workers and impoverished mountain workers and became involved in the labour movement and the education of labour union organizers and members. Horton and his young friends, who became the staff of the school, struggled to integrate their educational experiences into a way to educate adults and to deal with the problems of the South. They developed some residential educational programmes lasting from 6 weeks to 2 months. They continued somewhat formal courses but encouraged students to become involved in the community, attend union meetings and organize campaigns in industrial communities. They also had informal weekend conferences which were more discussion groups. Their practice of living, working and eating together broke down racial barriers.

Horton recalled how in the early days, despite their intellectual commitment to participatory educational practices, the young 'teachers' tended to follow the patterns learned from their educational experiences

and lecture the students. They found that this did not produce understanding, reflection or action, so they ‘learned from the people’ and developed a method which was participatory and transformational. Highlander’s education methods evolved through working with people and communities marginalized and underserved by the mainstream economy. What emerged was an educational process that allowed people to analyze problems, test ideas and learn from their experience and the experience of others. Horton was convinced that education must be communal and democratic and must emanate from the people. Education should be a process of creating a forum where people solve their own problems. Horton called the Highlander pedagogy *Education for Social Change*—a method which influenced not only the labour movement but also the Civil Rights Movement and environmental activism in the South, Appalachia and throughout the country.

In order for the staff to understand the problems of the workers in the textile mills, Highlander staff worked as labour organizers and in outreach programmes, working with former students in their communities or organizations. They helped other schools organized by unions for the training of their members. In 1937, Horton worked with the Textile Workers’ Organizing Committee as a labour organizer. In the process, he learned the difference between being an organizer and being an educator. He became very critical of the ways in which organizers sought limited goals to encourage and mobilize people to achieve short-term victories. He became convinced that Highlander should emphasize education over organizing. Organizing should occur with or after education, so that people would work for structural change rather than short-term goals.

Although illegal in Tennessee and throughout the South, all activities at Highlander were racially integrated. Highlander was a training centre during the Civil Rights Movement and was considered a ‘communist training school’ by southern segregationist governors. Martin Luther King Jr. and Rosa Parks were among the many to attend Highlander workshops, and the southern governors worked to close the school, thinking that closing Highlander would stop the Civil Rights Movement. After being closed by the State of Tennessee in 1961, the school was renamed as Highlander Research and Education Center and moved to Knoxville, Tennessee, then relocated in 1971 to New Market.

In the Highlander education process, factual information, critical analysis and people’s experiences were combined with dramatic skits and music, which included rewriting familiar gospel songs for the picket lines. Zilphia Horton added this to the core curriculum of the labour education programme. The same technique served the Civil Rights Movement, which included both the citizenship schools and the revision

of an old gospel song, which became the rallying song of the Civil Rights Movement: ‘We Shall Overcome’.

The Role of Research in Highlander’s Work

Highlander used research to involve people in the study of racial problems, in the farmers’ union co-operatives in the 1950s and later in Appalachian land ownership studies. Horton insisted that research, like education, must grow from the problems of the people, not from problems in the researcher’s head. It should be more than simply ‘technical assistance’ or ‘back up’. He never saw research as a one-time, completed project but rather as an ongoing process, a way of understanding the situation and working on problems.

Highlander developed a region-wide participatory research effort in the 1980s to study the ownership of land and minerals in the coal mining regions of West Virginia, Virginia, Kentucky and Tennessee. Community people from throughout the region were the researchers, and they met together at Highlander to train, to share their findings, to develop strategies to use the research and take action to change tax structures and to discuss land reform needs and possibilities.

Horton’s Later Work and Continuing Influence

When Horton retired from the Highlander staff, he had the time and freedom to visit places in the world with similar educational centres. He saw a role for Highlander to bring together people with shared backgrounds and concerns to work together on similar problems. Horton visited the Society for Participatory Research in Asia (PRIA), and there were exchange visits between Highlander and PRIA staff, which resulted in collaboration and international sharing. Union Carbide had chemical plants in Bhopal, India, and in Institute, West Virginia. Bhopal had a big disaster, and the West Virginia plant was facing a similar problem. PRIA and Highlander shared information and worked together with community groups in both places.

Horton and Paulo Freire knew about each other and recognized the similarities of their ideas and their experiences of learning and developing their methodologies many years before they actually met and shared their stories and ideas. Freire suggested that they ‘speak a book’ together, and he came to visit Horton at Highlander in 1987, and their conversation became a book, *We Make the Road by Walking* (1990). They talked about their educational philosophies and strategies; Horton talked about using questions as intervention and leading students to consider or deal with particular ideas. While Horton stressed beginning with the knowledge of the people and helping them learn

how to analyze their experiences, he emphasized going beyond the knowledge of the people. Freire talked about starting from where people are, to go with them beyond these levels of knowledge without just transferring the knowledge. Freire agreed that Horton's way of asking questions was a way of teaching content.

Horton's philosophy and practice of education and his approach to community-based research have informed and inspired new generations of action researchers, and his influence continues to be felt in the ongoing work at the Highlander Research and Education Center, which maintains his home there as a space for reflection and learning.

HUMAN RIGHTS

The UN defines human rights as those rights that are inherent to all human beings, regardless of nationality, place of residence, sex, national or ethnic origin, religion, language or any other status. Human rights include civil and political rights, such as the right to life and liberty, as well as social, cultural and economic rights, such as the right to practice cultural traditions,

the right to work and the right to education. In the twentieth and twenty-first centuries, human rights law developed, which includes treaties, international legislation, general principles and other sources. These laws describe obligations of governments to act to promote and protect human rights and freedoms of individuals or groups and to refrain from acting in ways that are deleterious to the inhabitants of their countries and other nations.

Some of the most important precepts of human rights are that they are universal, inalienable, equal and non-discriminatory. Despite the precept of universality, only 80 per cent of states in the world have ratified more than one core human rights treaty which binds them legally to obligations of protecting human rights of people in the world. Human rights are also described as being inalienable, which posits that they cannot be taken away. Important to note, however, is that these rights can be limited in due process situations. The human right of liberty, for example, may be restricted if a person is found guilty of a crime in a court of law. Every human being is believed to have equal rights regardless of group membership, geographic location, citizenship status and so on.

Human rights scholarship and legislation refer to many different rights, and the list continues to expand into the twenty-first century. The breadth of rights categorized as human rights, and the changing nature of human rights in scholarship and practice, contributes to challenges faced by the human rights movement on the world stage, as well as by researchers who strive to implement action research and Participatory Action Research (PAR) in the name of human rights, as discussed below.

Civil and political rights, for example, have been grouped together as first generation rights, with the understanding that the existence of these rights in political doctrine and scholarship across disciplines predates the adoption of the Universal Declaration of Human Rights (UDHR) by the UN General Assembly in 1948. Social, cultural and economic rights are referred to as second generation rights as their presence in the arena of human rights corresponds to the adoption of the UDHR. More recently, in the late twentieth and early twenty-first centuries, there are arguments for international human rights to consider an entirely new set of rights, labelled third generation rights. Third generation rights refer to the collective rights of societies, such as the right to sustainable development and to environmental health and safety. These rights are thought to be needed for societies in the majority world to be able to enjoy first- and second generation rights. The human rights scholar Burns Weston points out that human rights doctrine is changing as the ethos of human rights around the globe changes. Weston

explains, for example, that third generation rights were introduced as an increasing support was felt around the world for self-determination and the rights of minority and indigenous groups.

Historical Origins

Even though human rights scholarship and doctrine appear to be ever changing, most scholars and practitioners agree about the origins of the term *human rights* and about the philosophical origins of the human rights concept. It is widely accepted that the term itself came into being with the establishment of the United Nations in 1945 and the adoption of the UDHR in 1948. Scholars also largely agree that the general language of human rights came to replace *natural rights*, a concept introduced primarily by the seventeenth century philosopher John Locke. Scholars also point out that the concept of human rights is linked to philosophical questions about justice and morality, which can be traced to the writings and thought of ancient philosophers such as Aristotle and the Roman Stoics Cicero and Seneca. They also note that theoretical discussions of human rights are tied to more recent debates about moral reasoning and the capacity of human beings for moral reasoning, the focus of the eighteenth century German philosopher Immanuel Kant's work.

Contemporary Discussions of Human Rights as Natural Rights

Even though the influence of a great many philosophers on the development of a human rights concept is acknowledged, Locke and his *Two Treatises of Government* (1688) are commonly credited with laying the foundation for thinking about rights as a natural condition of being human and for the relationship of rights to political entities. For Locke, natural rights are the rights to life, liberty and property. Locke argued that these rights exist whether governments aim to secure them by contract or not. Since Locke, many contemporary debates that go beyond the confines of this entry have ensued about what natural rights mean for government and contemporary human life, as well as about the relationship between natural rights and human rights. Gary Herbert, a professor of philosophy, for example, has argued that while the concept of natural rights is linked to the concept of human rights, they differ significantly because natural rights do not impose obligations on others or encourage individuals to be concerned about the suffering of others, as the modern conception of human rights does. John Mahoney, a Jesuit priest and a human rights scholar, takes a different position, arguing that the right to protect one's liberty—a clear natural right—necessarily has implications for the

relations between human beings in a particular society and community. He notes that for certain liberties to be respected and protected, certain societal interventions are required. For Mahoney, natural rights include the involvement of other people as well as social, economic and cultural contexts in human life and are, thus, not so different from human rights.

Human Rights in the Twenty-First Century

Disagreement in the scholarly world about the exact nature of human rights, and their relationship to philosophical accounts of rights, persist. Scholars tend to agree, however, that since the passage of the UDHR in 1948, the ethos of human rights has shifted and human rights movements have gained in popularity throughout the world. This has occurred especially with regard to issues of economic justice and greater political freedom. According to Weston, there is now a deep concern for the promotion and protection of human rights across the globe. While 1948 may mark a decisive shift in global politics, additional contributions to human rights were made in the 1970s and 1980s. During these two decades, national foreign policies, and specifically that of the USA and President Jimmy Carter, began explicitly forwarding human rights agendas. Also during this time, international organizations such as Amnesty International and Human Rights Watch flourished, which sought to spread concern for human rights on a global level. Additionally, faith-based and professional groups increased that were committed to the human rights movement, and large international human rights conferences addressing human rights issues—such as the rights of children, population concerns, reproductive and women's rights, among other issues—proliferated.

Despite the increase in public support and concern for human rights, contemporary approaches to human rights in scholarship and practice vary. Marie-Benedicte Dembour, a human rights scholar and professor of law and anthropology, suggests that there are four different orientations to human rights in scholarly and activist communities. These are (1) a *natural* view of human rights, (2) a *deliberate* view, (3) a *protest* orientation and/or (4) a focus on *discourse*. The definition of human rights provided by the UN and the human rights initiatives led by the UN over the past century could be classified as corresponding to both a natural understanding of human rights and a deliberate view. This is because they suggest not only that all human beings possess human rights as they are natural to being human but also that human rights can only be sustained through deliberate social agreements within a global polity. According to Dembour, scholars and practitioners with a deliberate orientation to human

rights try to address this seeming contradiction by maintaining the hope that human rights will take on a universal nature, but only in time, when all people recognize human rights as an ideal form of law that should dictate political and societal life.

The third school of thought identified by Dembour, the protest school, may be the one that is the most relevant to action research. This area utilizes human rights as a means for making claims on behalf of the poor, marginalized and oppressed to redress injustices in the world. Similarly, action research scholars often utilize research and academia, and the power they experience through both, to affect social change processes and advocate for human rights. On a more extreme plane, but not necessarily antithetical to protest scholars, are human rights researchers, practitioners and activists who view human rights arguments and human rights movements instrumentally. These discourse scholars use human rights to push for social justice without believing in human rights as a natural condition of being human. These scholars and practitioners, according to Dembour, are more likely to believe in other forms of liberty and equality that are not bounded by the complexities of human rights. This could include scholars who push a *cosmopolitan* agenda, such as Kwame Anthony Appiah, arguing for uniting different peoples and cultures of the world, but not necessarily on the basis of human rights. Included in this group of discourse scholars may also be researchers such as Mahmood Mamdani, who warn that human rights movements and interventions bring with them the threat of imperialism and a new form of colonialism in the twenty-first century.

Challenges at the Intersection of Human Rights and Action Research

Human rights researchers and activists have much in common with participatory and action researchers and are often one and the same. These scholars are referred to as activist-academics. M. Brinton Lykes, for example, is simultaneously a participatory and an action researcher, a community-cultural psychologist, a human rights scholar and an activist. At the intersection of all these things, Lykes serves as an associate director of the Center for Human Rights and International Justice at Boston College, as well as a faculty member in the Lynch School of Education at Boston College.

It is no coincidence that participatory action researchers, like Lykes, are also often human rights activists. This is because PAR, as an alternative form of social science inquiry in the twentieth and twenty-first centuries, developed as a part of human rights and social justice movements in the twentieth century. While some trace the origins of action research to Kurt Lewin's work in the USA around organizational

behaviour, those involved in action research and PAR in the majority world see Latin American activists and researchers, such as Paulo Freire (1970) and Orlando Fals Borda (1985), as responsible for the creation of PAR. It is, therefore, not surprising that participatory and action researchers often confront some of the same challenges as human rights activists and scholars.

In PAR projects, a goal is often for members of the academic world to unite with members of a community with whom they are interested in working, as co-researchers in a project, and to collaboratively investigate social phenomena or problems affecting the community. Despite sharing the goals of social change and social justice, when different cultural groups come together on a PAR project, the fear of the protest- and/or discourse-oriented human rights scholar—that human rights agendas will be imposed on a particular community—comes to the fore.

In one such PAR project initiated by Lykes, titled 'Human Rights of Migrants: Transnational and Mixed-Status Families' (as described on the Center for Human Rights and International Justice website), these challenges were present. The goal of the project was to protect the human rights of Central American and Mayan immigrants in the USA who were experiencing threats of detention and deportation, yet other human rights issues arose during the project. These issues related to the participation of women as co-researchers in the PAR project. As occurred for members of this study, and as frequently occurs during participatory research that brings different cultural groups together, human rights issues of concern to some of the co-researchers on the project were not of concern to others.

A dilemma shared by action research and PAR, and the human rights world more generally, is, thus, whether human rights agendas should always be encouraged even when communities involved in a research project do not otherwise recognize or share the same human rights concerns. Put differently, the practical challenges of human rights-based action research that brings together culturally distinct communities reflect the debate in scholarship and practice on universal human rights and cultural relativism.

Human Rights and Cultural Relativism

Cultural relativism asserts that human values emerge in particular social, cultural, religious, economic and political contexts and therefore differ from one community to the next. This perspective also posits that because human values vary a great deal according to the group to which one belongs, applying human rights as a global ethic or legislative system cannot be done without great difficulty and, in some cases, disregard for cultural freedoms.

Human rights scholars, such as John Mahoney, argue that despite respect for cultural diversity being at the heart of human rights legislation, cultures and states are not ethically sacrosanct and above ethical critique or challenge. Mahoney, referencing the words of the former US Secretary of State at the UN Vienna Conference on Human Rights in 1993, explains further that we must respect the religious, social and cultural characteristics that make each country unique without enabling claims of cultural relativism to become the last refuge of repression. He argues, for example, that even though clitorrectomy can be tied to tribal mores or cultural practice, it is still gross bodily mutilation that can be likened to other forms of punitive amputations. This case is one, according to Mahoney, wherein the protection of human rights must supersede the imperative of equally respecting all cultures.

A middle ground taken by some cultural relativists and human rights scholars in this debate is that scholars and practitioners should aim to strike a balance between respect for cultural freedoms and the protection of human rights. The human rights scholar Tom Zwart suggests that through collaboration between international legislative bodies and local sociocultural institutions, human rights protections can be put in place internationally and in a way that is culturally respectful and effective.

Similarly, as the human rights scholar Sally Merry has argued, much of the language in international human rights legislation in its current instantiation frames cultural practices in the Global South as if they are backward and, in some cases, oppressive, whereas cultural practices in the Global North are framed as if they reflect the highest ethical standards. Merry cautions that this subtle ‘othering’ may further alienate individuals and nations who engage in these practices from the language and legislation of human rights, rather than striking some balance between respect for traditions and universal ethical standards worldwide.

Nonetheless, Merry and others note that if cultural tradition alone governed how states did or did not comply with international human rights standards, there could be widespread abuse and violation of human rights in the name of cultural and other forms of freedom. They also note that defending punitive practices in the name of respect for cultural diversity could pose a dangerous threat to the effectiveness of international law and the international system of human rights that has been carefully constructed over the past several decades.

This debate is alive and well in both activist and scholarship arenas and highlights the complexities of participatory and action research collaborations throughout the world.

Even though activist-academics, human rights scholars and activists have different views on this

subject, these questions must be grappled with to prevent action research and PAR from becoming another instance of imperialism in the research world. This is essential for participatory research processes as imperialism in social science inquiry, and the world outside of it, is just the sort of injustice that these research processes seek to redress.

HUMAN SUBJECTS REVIEW

See Institutional Review Board

HUMANISM

Humanism refers both to a mindset and to a movement with invaluable significance to Western culture. The

term was created as the Latin translation, *humanitas*, of the Greek core concept for lifelong learning, *paideia*, probably by Cicero. Humanism is the programme of thinking which forms the urges and the modes through which we respect and seek knowledge in the other person. It is the core of relationally informed dialogue and hence the precondition of action research. This entry presents humanism as a mindset and as a movement and explains the changes in ontology, epistemology and politics to which it gives birth.

The Mindset

As a mindset, humanism, on the one hand, denotes a level of education through which the individual is empowered to take care of himself or herself, *cura sui*, and to act responsibly on behalf of the community, the *communitas*. Consequently, both the mastering of civil virtues and knowledge of history, language and law, and the martial arts too, were implied in this education, from which the concept of ‘the humanities’ as a branch of science was later formed. On the other hand, *humanitas* also meant a moral or ethical attitude, the core of which was generosity, the *generositas*. It was closely connected to Cicero’s concept of equity, *aequitas*, an attitude expected from judges under Roman law, through which they had to perform by the guidelines to consider the situation of the offender before and during the crime. Deduced from Aristotle’s concept of *epieikeia*, from *Nicomachean Ethics*, the ideal of equity might even surpass the claims of empathy and mean magnanimity.

The core of the mindset of humanism today could be expressed as the endeavour to seek liberation and empowerment for oneself and others through knowledge and to relate with understanding, care and generosity to every single human being. The right to autonomous expression of one’s emotions, values and interests is pertinent to humanist endeavours. In these attitudes, analogies can be found in the aspirations of action research to understand the view of the other person.

The Movement

The movement has its origins during the period of antiquity in Classical Athens, spreading during Hellenism to more cities and finally to Rome. To conceive and treat everyone as a human being, irrespective of ethnic, national or linguistic origin and regardless of world view, was anticipated by Stoicism but was transformed into a perspective virtually covering the whole world by Christianity—with a little help from Roman imperialism. However, the sense of humanism as a movement is bound to the Renaissance, the Baroque

and the Enlightenment. Historically, these periods are characterized by the power reduction of the Catholic Church, and hence of its ideologies, and by the forming of national states with civil rights. Political and social rights could also be seen as, among others, a consequence of a developed, differentiated and pervasive humanist attitude, but they belong to the past two centuries.

Humanism has often been seen as a process in which the individual becomes conscious of his powers and dares to pursue his talents and interests in spite of the ruling hegemonies of thought and the social hierarchies. One speaks about the typical ‘Renaissance man’, incorporating artistic talents, technical and scientific capacities, poetical skills, knowledge of languages and a profound philosophical attitude. Baldassare Castiglioni prescribed this ideal of the humanist gentleman in his 1528 book *Il Cortegiano*. Painters, sculptors and architects became the idols of humanist Renaissance in Italy. It was not until the Baroque, however, that humanism was identified with the ideal of accepting the other person, her culture, values and integrity, and with nurturing and emphasizing mutual understanding through dialogue.

The New Fabrics of the Three Essences: Nature, Humanity and Society

The transformation of the concept of cosmos from geocentric to heliocentric through Copernicus is closely related to humanism. Although many of the transformers in science were still devout Christians, the concept of the power of God was reduced by these discoveries, and the faith in human beings to master their own fate increased considerably. This, of course, could not help but influence the way humanity, and indeed human nature, was conceptualized. Giovanni Pico della Mirandola’s *Oration on the Dignity of Man* (1486) defined the core of Renaissance humanism by claiming that while everything else was subject to change, human beings, through their formation in the image of God, had the unalterable capacity to change themselves by will. The famous Renaissance concept of *virtù*, the force of action inherent in the prince according to Niccolò Machiavelli, developed in turbulent Catholic Italy and was not embraced by the Protestant movement, in which one relied alternatively on the mercy of God or on determinism. Humanism eventually came to represent the contrary attitude here: the belief in free will, as advocated by Erasmus against Luther, and the reservations towards determinism. However, a pre-democratic spirit of individual freedom could be found in Protestantism, which manifested itself in the belief that any man or woman is responsible for himself or herself towards God, without any mediation by religious institutions.

Pietism, conservative or utopian, shared one set of attitudes with humanism: care for others, mildness and pity. The belief so important to humanism that humans are by nature good probably began in such circles, as did the serious attempt to find an alter ego in any other human being beyond social class.

The Political Consequences of Humanism

Further, humanism had to incorporate itself in a concept of humans as political beings in order to establish itself. Hence, it was closely related to the grand theories of natural rights to life, liberty and property and the law of nature developed by Hugo Grotius, Thomas Hobbes, Baruch de Spinoza, Samuel von Pufendorf and John Locke (the last three were born in the same year, 1623). This created the foundation for the core of humanist anthropology, the *lux naturalis* or *lux rationis*, the 'light of nature' or the 'light of reason', inhabiting every single sane human being. This capacity made individuals untouchable in principle, unless they betrayed their integrity by disobedience to the collective manifestation of the light of reason, the law. Humanism during the Renaissance and the Baroque was rather loyal to the establishment, although critical towards its mores and its institutions, but during the eighteenth century, it became deeply involved with three revolutionary projects.

Revolutionary Humanism

The aims of revolutionary humanists were the liberation of knowledge from religious and political dogmatism, the vindication of human rights and the destruction of feudal society through a republican constitution and new social institutions. Charles-Louis de Secondat Montesquieu's book *De l'Esprit des Lois* (1748) presented the idea of the partition of powers, which was anticipated by Locke.

The work of Cesare's (the Marquis of Beccaria-Bonesana) treatise *On Crimes and Punishments* (1764), condemned torture and the death penalty and prepared the reformatory French Penal Code of 1791, adopted during the revolution.

During the Enlightenment, humanism became more generally involved with the idea of progress of the human mind, as advocated by the editors of the French Encyclopedia (1751–72).

Humanist Epistemology

Epistemology underwent its first formal and immensely important development in the opera of Plato and Aristotle. Linguistic philosophy and theory of language underwent a subtle development by

Stoicism almost at the same time. The distinction between theoretical and practical philosophy is the pivot of Greek epistemology, and consequently, ethics and politics become subjects in the very process of developing the concept of praxis. Neo-stoicism during the Baroque incorporated Stoic ethics as the core of humanist attitudes, among others in Justus Lipsius. An important concept in both Plato and Aristotle is *phronêsis*, often translated as 'practical wisdom' or 'practical knowing', the realization of the *sensus communis*. Since it has a normative core, combining values and experience, it is also of great influence to the humanists' ideal of wisdom. It has gained increasing significance in the field of action research, since it also advocates research guided by the sense of situation, by intuition and by the courage and capacity to practice the phenomenon which Charles Sanders Peirce called 'abduction' and Aristotle, the syllogism of rhetoric, the 'enthymeme'.

Humanism was formed by the rediscovery of first the Latin and then the Greek philosophical and rhetorical heritage. Language has more important functions here, but primarily, it prepared a hermeneutical mindset, the core of which is interpretation as an epistemic function, which has shaped the humanities and later on also was to be a driving force of action research through the influence from phenomenological philosophy. Even if language still had to serve logic and argumentation within a dogmatically closed framework, in which sense-experience did not rank highly, new sensitive and absorbing relations between the world of the senses and the world of words were prepared. Empirical studies could thus arise as a branch of humanism, already realized by anatomical studies through dissection in fourteenth century Bologna. The terminological creativity of Francis Bacon in his *Novum Organon* (1620), his programme for an empirical science, is a case in point.

In the humanist mindset, lifelong learning, and hence education, had priority. This was not just due to the tradition of rhetoric which dominated education far into the seventeenth century. Humanistic education, also named liberal education—the *studia humanitatis* and *artes liberales*—placed tremendous weight on the knowledge of classical languages and philosophy and strictly belonged to the ruling classes and the more wealthy sections of the bourgeois. A democratic ideal, related to humanist Protestantism, of educating the common man and woman emerged already during the Baroque in Johann Amos Comenius' revolutionary focus on early education but did not achieve real influence until 100 years later with the work *Émile* by Jean-Jacques Rousseau (1762). Later, the work of John Dewey pursued the ideal of combining theory and practice in education and in philosophy, defining

experience as an aesthetic of character, and hence inherently practical.

In the religious field, humanism advocated tolerance, often deism, like Francois de Voltaire, or a universal God beyond the claims to truth by revelation, like Gotthold Ephraim Lessing.

The Forces of Dialogue

During the twentieth century, the humanist ideal of dialectical dialogue was revived in so-called dialogue-philosophy, in which the ideal of the capacity of interlocutors to create a deep mutual understanding was developed. The capacity to ‘really’ meet each other created new conceptual frameworks through a cooperative experiment in learning. Important philosophers were Martin Buber, Gabriel Marcel, Emmanuel Lévinas and Jürgen Habermas and the psychologist Carl Rogers. Such dialogue is at the heart of action research’s emphasis on participation and collaborative practices.

Beyond Humanism

Martin Heidegger’s renowned essay *Brief über den ‘Humanismus’* (2000), written during the post-war era, contains a rather radical criticism of humanism for not appreciating the essence of human beings sufficiently and for being too anthropocentric. He argued that what any man or woman might be is something which we cannot deduct from his or her practice and achievements so far: It is an ongoing, irreducible phenomenon. The respect towards other persons, towards other experiences, towards cultural settings and towards nature (ecological considerations) displayed by action research shares some of these concerns and thus

contributes to an understanding of the human and the world in which he or she participates, both as ‘being’ and as ‘becoming’.

IDENTITY

Identity is a term laden with a range of meanings by scholars and practitioners, but two understandings, both relevant to action research, regularly surface. Identity can refer to core aspects of an individual—that is, what we or others view as our essence or nucleus. It can also refer to particular, pre-existing (though socially constructed) categories, including societal groups, such as gender or race; professional and occupational affiliations, such as researcher or farmer, and roles, such as manager or father. Identity has been inherent in action research since its inception because it is based on the idea that research can be pursued by those who do not identify as scholars. By design, action research brings together people with different identities—researchers and practitioners or insiders and outsiders—as part of the research process. But identity may come up in other ways as well; for example, many action researchers document conflict related to divided organizational loyalties or their own struggle with issues related to class, gender or race.

The degree to which such issues are actually engaged with ranges across approaches, especially depending on whether the research is first, second or third person research. First person research involves researchers studying their own practice; second person research is undertaken by small groups exploring individual- and group-level practice; third person research is the most similar to traditional research in that a research team (which may include scholars and/or community members) studies a separate group of individuals. First person and second person researchers customarily grapple with the implications of identity—implicitly if not explicitly—while third person researchers vary in their take-up of these concerns. This entry reviews (a) how action researchers tend to characterize identity, (b) common questions and concerns related to identity faced by researchers and (c) methodological issues and approaches.

Characterizing Identity

Action research convenes researchers and practitioners because, in part, it is based on the idea that identity affects the standpoint, or one's perspective. That is, identities function as lenses or frames that help us see some things while they obscure others. All standpoints are partial; no one is omniscient. That is the rationale for bringing together scholars and laypeople or insiders and outsiders: They will bring different and complementary insights which can create a fuller—though never complete—picture.

Many action researchers also complicate the notion of identity as standpoint in several ways. First, identities are viewed as multiple and fragmentary. As researchers, we may simplistically assign people to a category but find that those ascribed reject the label. Second, identity is constructed. While we often think in terms of taken-for-granted categories—men and women, doctor and patient, marketing and engineering—in fact, those categories are created and sustained through social interaction and are, therefore, malleable. This means that the research process itself may contribute to the blurring or reinforcing of categories. Finally, identity, and therefore standpoint, is commonly seen as fully bound up with power. Standpoints are not neutral, nor do they vary idiosyncratically; they serve some interests and not others. Moreover, identities confer or diminish power, with consequences for the authority accorded their point of view.

These characterizations of identity come into play as action researchers face basic questions and decisions related to identity in their research.

Researching Identity: Key Questions and Decision Points

While every action research project is unique, certain questions pertaining to identity emerge across studies. These interrelated questions include the following: Whose identity? What identities are explored? Is

identity the named area of study, or does it come up as a by-product or side effect—as an ‘uninvited guest’?

Members of an action research team must begin with a basic choice about whose identity they are studying: their own or others’. First and second person action research is designed to explore the self (or multiple selves), while third person researchers focus their inquiry on others. Many scholars intertwine strands of first, second, and third person research.

While any number of identities could be studied, research tends to cluster on several particular ones. First, the identities of researcher/university member/scholar and practitioner/community member/layperson are, not surprisingly, the most common area of inquiry since they are immanent in action research itself. Studies inquire into frames or assumptions held by the two groups, the kinds of conflicts that arise between them and the conditions that enable productive resolution of disagreement. A closely related set of identities is insider and outsider. Most often, the outsider is the researcher and the insider is the practitioner or community member. Similar to scholar/layperson, these kinds of studies explore their different perspectives and the possibility of confluence. Some researchers explore these topics by looking at the complexities and contradictions of being both insider *and* outsider, both academic *and* layperson.

Another common arena is various social identities, such as race, ethnicity, gender, class, ability/disability, LGBT (lesbian, gay, bisexual or transgendered) and the like. Within this group, gender may be the most commonly explored, with the intertwined grouping of race, ethnicity and culture a close second. Some researchers study the intersectionality of identities, such as race and gender or gender and class. The foci of such studies vary broadly. Some researchers engaged in first person research study the impact of their own identity on the research process, such as the kinds of questions they asked and how they made sense of the data. One form of second person research is a group of people from a marginalized group, such as people of colour or the disabled, exploring how to overcome their disenfranchisement or feelings of disempowerment. Another kind of second person research investigates how people with two different and often conflicting identities, such as two cultural or religious groups, manage to bridge their differences—or fail to do so. In third person action research, a researcher might work with a group of people on an inquiry into their structural constraints or an intervention in their community. Unlike more traditional research, they might focus on how participants’ views and real-life conditions corroborate or contest popular discourse about their group, whether they are low-income African Americans, homeless men or teenage girls in rural Pakistan. Sometimes, researchers define a community in one way only to discover that

group members find other, intersecting identities to be more salient.

Finally, a connected issue is whether identity was a named focus of the original research or whether it came up as an unavoidable topic as the data collection or analysis got under way. Many studies are designed to, for example, explore a stymied policy change effort or the process by which organizational members conducted a self-evaluation, but then, they raise issues related to identity, which then becomes a theme in the write-up. This is identity as ‘uninvited guest’, meaning that it may have been seen as an intruder interfering with the ostensible focus of the study but ultimately was welcomed as an essential area to explore.

Methodological Concerns and Approaches

Action researchers studying identity face many of the methodological concerns facing those studying other topics, though the particular manifestation may vary. One common issue is voice, or the way the author or authors represent themselves in their writing. A second is validity, or how the quality of the research can be assessed. Further, those studying identity may also draw on particular approaches to data collection and analysis, especially approaches that emphasize community participation.

The authorial voice has many dimensions. One way it arises is the question of whether the voice should be univocal or multi-vocal—that is, whether the writing should include one or more distinct, differentiated perspectives. Given that identity creates standpoint, representing multiple points of view in the writing can feel truer to the basic ethos of action research. Including multiple views may also be a way to ensure that perspectives that are often marginalized—from community members, poor people or people of colour—are represented along with those of more powerful groups. However, some scholars have argued that authors should not privilege the voices of practitioners to the extent of occluding their own.

In first person research, the decision regarding one or multiple voices is usually straightforward since the author is writing about himself or herself and therefore uses his or her own voice. However, some first person research includes comments from others (taken from interviews, e-mails or other communication) that the author brings in as data and integrates into the narrative. Single authors conducting first person research can also present themselves as multi-voiced by, for example, quoting from journal entries written in the past and juxtaposing them against a more current stance or interpretation.

Second person research, by definition, raises more complexity. As research by a group on itself, it should

be written by the group, but this begs the question of whether the group should speak with a single voice or multiple voices. In some cases, authors choose to create a synthesized voice that speaks for all; in others, individual voices may be heard at various points. Usually, the individual authors are listed by name, but occasionally, a group chooses to publish under the name of the group itself.

Third person researchers must also deal with whose voice is represented. Some studies stress solidarity within groups, while others document within-group conflict and power dynamics with a multi-vocal analysis. Moreover, some research explores how the researchers' identity, however understood, influenced the dynamics between them and the group under study. The lead researchers must also identify which aspects of the study were co-shaped by others in the group. The voices of multiple group members may figure prominently, but the overarching analysis and final narrative is usually the researcher's.

Establishing validity in action research is an ongoing concern. While researchers mention a number of different assessment criteria, two stand out as particularly relevant to identity-connected inquiry. The first is visceral personal experience: Does the research feel true to those it describes, whether oneself or others? Unlike many other research topics, identity is ultimately rooted in the self, in authentic, lived knowledge. Therefore, personal reaction can play a greater role than it might under other circumstances. The second is whether the research speaks beyond just one person to multiple audiences with very different backgrounds and life experiences. Identity research can delve into one person's or one group's life experience but then radiate multiple stories that reach a disparate group of listeners.

Action research runs along a continuum from approaches that give virtually full control to university members to methods that emphasize full and equal participation by community members. Identity-related research tends towards the more participatory end of the axis, perhaps because distant, detached approaches are less able to fully document or comprehend something as personal and intimate as identity. First and second person approaches are, by definition, participatory: There is no distinction between the researcher and the researched. Third person research uses various ways to ensure participation by the study's subjects. The most common are participatory appraisals, journaling and mapping exercises and arts-based projects that call upon participants to draw upon traditional media (e.g. quilting) or photography to examine contemporary tensions. For example, the researcher might present data in non-technical, accessible ways, often via visual modes. Participants might then document their own

conditions and responses to the prompts, often using arts-based approaches.

Ultimately, identity is fundamental to the practice of action research; the question is how and how much scholars actually engage its impact and complexities.

INDIGENIST RESEARCH

Indigenist research is a form of social enquiry based on the principles and philosophies of indigenous peoples, adopted by indigenous people and designed to be conducted by indigenous people within their own communities. Its primary purpose is to allow indigenous people to represent their worlds in ways they can only do for themselves, using their own processes to express experiences, realities and understandings that are unique to indigenous society, history and culture. It achieves this purpose by drawing on indigenous philosophical understandings of the world and places itself against what is seen as an imposed (Western) view that does not acknowledge indigenous ontology and epistemology. It is an inherently political activity that critiques the assumptions of colonial constructions and understandings of indigenous society and culture.

Indigenist research comprises a range of methodologies for engaging individuals and communities in research, usually from an intra-society perspective

rather than for external interests. It presents a culturally specific way of empowering indigenous people as the creators and collectors of knowledge and information rather than as the providers of information to others. Furthermore, its core purpose is to allow indigenous communities to engage in creating their own history and understandings of culture in ways that are internally consistent with the ontologies and epistemologies of that culture and that deeply engage with their experience of events and social process, expressing them in language, narrative and styles that are culturally appropriate. It provides the intellectual context, language and rationale for research as a whole-of-life and fundamentally political engagement with the world. In this way, it reflects the principles of action research, allowing for context-specific communal self-development and empowerment amongst indigenous communities. This entry reviews the history and development of indigenist research and the epistemological foundations and principles of this form of research, emphasizing the importance of social relationships in indigenist research. It then examines the relationship between indigenist research and action research and the role of indigenist research in achieving positive change.

History and Development of Indigenist Research

Indigenist research has emerged as an alternative mode of engagement with knowledge to the dominant mode of Western research. It arose from a need to challenge outsider views of indigenous cultures, especially where these views sought to research culture for outsider purposes (e.g. in anthropological, ethnographic or scientific studies of indigenous people, communities and societies). The Māori indigenist researcher Linda Tuhiwai Smith has observed that for indigenous people the term *research* is intimately linked to European imperialism and colonialism and that in a colonial context—in other words, societies within which all indigenous people now live—Western research remains a tool of power and domination, legitimating former colonial social relationships and intellectual traditions and the commodification of knowledge. For Smith, there is an urgent need to view the world through non-Western eyes (e.g. a ‘history of Western research through the eyes of the colonized’) and a need for an intellectual tradition in which the researcher undertakes a historical and critical analysis of the role of research in the indigenous world.

Foundations of Indigenist Research

Key indigenous writers include Linda Tuhiwai Smith, Norman Denzin, Lester Irabinna Rigney and Errol West. During the 1990s, these writers established and published

concepts of indigenist research as being culturally safe and culturally respectful, driven by three key principles: (1) resistance as an emancipatory imperative, (2) political integrity in indigenous research and (3) privileging indigenous voices. The Australian Aboriginal researcher Karen Martin describes indigenist research as research that is proactive, progressive and visionary, that

- recognizes indigenous world views, knowledges and realities as distinctive and vital to indigenous existence and survival;
- honours indigenous social mores as essential processes through which indigenous people live, learn and situate themselves as indigenous people in their own lands and when in the lands of other indigenous people;
- emphasizes social, historical and political contexts which shape indigenous experiences, lives, positions and futures and
- privileges the voices, experiences and lives of indigenous people and lands.

The Importance of Social Relationships in Indigenist Research

Underlying this approach is the core principle that indigenist research must reflect indigenous, rather than Western, ontologies and epistemologies. While there are practical elements that indigenist research shares with action research, it only maintains its internal logic through its intellectual framing within indigenous ontology, distinguishing it, as Martin has noted, from simply being Western research conducted by indigenous people. Indigenous ontologies, while specific to individual language and kinship groups, tend to be relational—that is, they are predicated on awareness and a sense of self, on belonging and on responsibilities and ways to relate to the self and to others. In short, they provide an intellectual basis for people’s attention on their interrelatedness and their interdependence with each other and their greater surroundings. There are two further important consequences of this world view, which distinguish indigenist research from Western research. First, authorship does not equate to authority but provides a medium for articulating cultural knowledge already expressed through story, dance, song and so on. Second, cultural tradition both informs and affirms or validates the findings and expression of the indigenist research.

In these terms, social processes and relationships are of utmost importance in the conduct of indigenist research. Indigenist research commences with the deliberate and explicit identification of the person engaging in the research as an indigenous person first and as a researcher second. In doing so, it defines the form of possible research and, importantly, provides context

for the relationships between the indigenist researcher and the people with whom he or she is engaging. This stance places the researcher in a position of empowerment rather than reactive resistance, while it represents an alternative perspective for understanding the world. Indigenist research is more about empowering communities than about opposing alternative ideologies.

Research Methodology

In common with action research, indigenist research must locate itself in its context, the researcher locating himself or herself in the community's country. Country is understood to be not only the land, waters and biotas of the place but also all entities and the spiritual and legal systems of that place; the researcher is the country, and the country is the researcher. Research is conducted with due respect for traditional customs, ceremonies and authorities. In establishing an indigenist research project, the researcher carefully defines these relations as a basis for articulating a research theory and the research problem. Martin describes this research activity through three main constructs and their processes: (1) establishing, through (indigenous) law, what is known about the entities; (2) establishing the relations amongst entities and (3) enacting ways for maintaining these relations. In Western terms, these may be known as ways of knowing, being and doing. Ways of knowing include methods of observation and engagement, and are context responsive and purposive; there are different types and levels of knowledge; they serve social group and network functions and provide a basis for ways of being. Ways of being define relationships, determining and defining rights to be earned as individuals conduct rites to country, self and others; they evolve as contexts and life stages evolve. Ways of doing provide a synthesis of ways of knowing and being, and are expressed through language, art, imagery, technology, traditions and ceremonies, land management practices, social organization and social control.

Each indigenist researcher structures his or her description of an indigenist methodology in different ways. These descriptions, however, always reflect the essence of indigenist research—that is, it is community based and addresses the research needs of that community in ways the community fully understands. Martin provides a framework comprising eight key methodological elements: (1) research assumptions, (2) research questions, (3) literature review, (4) research design, (5) conduct, (6) analysis, (7) interpretation and (8) reporting and dissemination. While these may appear familiar to non-indigenist researchers, reconceptualizing these in indigenist terms provides a framework for an indigenous research agenda aimed at achieving social revitalization and empowerment.

This agenda focuses on, in order, resetting, reclaiming, re-viewing, reframing, re-searching, revisiting, reconnecting and re-presenting through research. In practical terms, Smith closes her book with a list of 25 indigenous projects. The titles reflect the convergence of indigenous ontology, epistemology, social process and interrelationships that characterize indigenist research as it is harnessed to address indigenous research needs: claiming, testimonies, storytelling, celebrating survival, remembering, indigenizing, intervening, revitalizing, connecting; reading, writing, re-presenting, gendering, envisioning, reframing, restoring, returning, democratizing, networking, naming, protecting, creating, negotiating, discovering and sharing. These titles reflect the importance of indigenist research in addressing issues of importance to indigenous people using processes and methodologies that reflect the power and knowledge inherent in these communities.

INDIGENOUS RESEARCH ETHICS AND PRACTICE

The leadership and meaningful involvement of indigenous peoples engaged in research is rapidly evolving. This is occurring within the context of indigenous

peoples around the world continuing to thrive despite often long histories of colonial interference. Written by a First Nation community-based researcher, this entry offers an introductory discussion regarding indigenous research practice and ethics. Drawing upon the values that are further described below, a perspective is offered regarding the fundamentals of developing and sustaining good research relationships.

Introduction

Self-Location

As a basic principle, knowing who is engaging in research and where they are from is essential. In contrast to Western European sociocultural restrictions (where talking about oneself is often interpreted as a sign of arrogance), properly introducing oneself to others is a way of respectfully acknowledging the ancestors who have come before us. It opens the dialogue with others to identify possible family or clan ties and begins the process of creating a relationship. The importance of beginning in 'a good way', or in a manner that is respectful of the territory where work is to unfold, is essential for everyone engaging in a research project.

Self-location as a concept requires briefly sharing details about one's self. This offers context and clarifies the position of the person involved in a project from the outset of shared work or presentations. Is an Aboriginal person leading the project? What Nation and territory is he or she from? What might this knowledge tell the participant, the community, a reviewer or someone planning action based upon the findings? What insights might be drawn about the perspective, understanding and assumptions the person might bring to the research?

Knowing, for instance, that this entry is written from the perspective of a community-based First Nation researcher's perspective positions the following comments within a certain context. The fact that the author lives, works and engages in research from sea-to-sea-to-sea in Canada may offer further insight. Finally, knowing that the focus of the author's research lies in the field of health, specifically HIV/AIDS, may contribute towards further grounding the roots of the story being offered in the following pages.

A Word on Terminology

Definitions are also useful. As a people who have been labelled by others, many times in foreign languages, knowing how words are being used is important. In Canada, the term *Aboriginal* is used as an umbrella term for the three categories of First Peoples within the boundaries of what is now a nation state. First Nations (or Indians), Métis and Inuit populations reside across the country bordered by the Atlantic, Pacific and Arctic

Oceans. Within each of these populations, there is great diversity: over 800 different communities, many different languages and unique customs and ceremonies.

Internationally, the term *indigenous* is used to respectfully refer to the First Peoples of a territory. As an inclusive term, *indigenous* is used in the language of the United Nations as a reference to the more than 370 million First Peoples throughout the world. The United Nations *Declaration on the Rights of Indigenous Peoples* specifically does not define who are indigenous peoples, in the interest of respecting the right of indigenous peoples to self-define themselves. In the interest of respectfully engaging in an international dialogue, the term *indigenous* will be used here.

The term *community* is also often referenced; therefore, some reflection upon the meaning of this word may be useful. Simply stated, communities evolve in a variety of ways with a variety of people. Indigenous communities may be described as a group of people who have lived in the same area/territory for a long time (e.g. precolonization) and have a shared history, a distinct language, family and clan ties, political structures and shared customs and traditions that are unique and different from those of the national/state population. *Community* may be defined by the specific Nation of indigenous people, such as the Mi'kmaq Nation; by membership within a grouping of indigenous populations, such as Australian Aboriginals or Torres Strait Islanders; by geographic boundaries, for instance, tribally controlled lands, or by reference to indigenous people who unite regarding a specific issue, such as HIV/AIDS. In urban settings, community may evolve as indigenous peoples from different territories come together through service organizations or meeting places. Nations exist within groupings of indigenous populations, and communities of interest exist within geographic communities, and this fuels the dynamic and complex web of communities within communities. More broadly, stepping back to consider the application of the term *indigenous community* in a global context, the definition becomes inclusive of all the groups of people living in different states who share a common world view of interconnected relationships and responsibility to the places where they are considered to be the first inhabitants.

Being Indigenous

Finally, there is the contentious issue of who is permitted to refer to themselves as indigenous. It is well beyond the immediate scope of this entry to answer the complex questions of identity. In Canada, and other countries in the world, official identity is based upon government regulations and lists. This is a colonial practice that negates the right to self-determination and strikes at the core of nation building by explicitly limiting

who does and does not belong as defined by powers external to the indigenous community. In simple terms, it is accepted that those who self-identify as indigenous, and are accepted by others who self-identify as indigenous, belong.

History

Researched to Death

Research is laden with tradition. Within the indigenous community, these traditions include the silencing of the indigenous voice, the disrespect of protocol and customs, the theft of traditional and/or community knowledge and the justification of colonial expansion into lands that were already inhabited by thriving civilizations. A long history of academic careers being built upon publications about indigenous people's lives and culture, whether accurate or not, has left a deep scar upon the international indigenous community. 'Helicopter researchers', who swoop down on a community, gather data and perhaps physical samples and then take off again without returning to discuss or share their findings have underpinned many of the relationships between indigenous communities and academic research. The appropriation of intellectual property and traditional knowledge about the medicinal properties of plants, for instance, has led to the exploitation of natural resources, with little or no benefit to the knowledge keepers themselves.

Leading indigenous health researchers including Linda Tuhiwai Smith (Māori, New Zealand) have written about research as a dirty word in the vocabulary of the indigenous community, and many indigenous people will speak about the feeling of being researched to death. This was literally so in the context of the introduction of foreign diseases and the destruction of traditional territories as eager researchers 'discovered' new indigenous Nations without considering the implications of contact and development—and figuratively so as streams of researchers documented and detailed daily life and death, the rise of poor health and the impacts of colonization (e.g. forced relocation, removal of children and policy- and law-limiting human rights) without lending support or discussing possible community-defined interventions. There is a sense that the research practices of the past have offered little other than attempts to disseminate sacred knowledge—(un)intentionally introducing and then documenting a community's struggle.

Researching Ourselves Back to Life

The times are changing. Research has always been a part of the lives of indigenous peoples and the sustainability of our communities. Western European-based

academic practices and doctrine are not the only way to undertake research, and moreover, they can be moulded and shaped to more accurately document different ways of seeing and relating to the world. The power of research to inform decision-making, to verify and validate a process or approach and to convince others of one's truth has not been underestimated by indigenous peoples.

The formal introduction of decolonizing research methodologies began to appear in literature in the 1990s. *Decolonizing Methodologies*, written by Smith and first published in 1999 (a second edition, published in 2012, is now available), became a foundational text for indigenous scholars. Increasing emphasis upon the ancient capacity of indigenous peoples to know the world around them is fuelling a new cadre of indigenous researchers who are grounded in two worlds—that of the indigenous community they are a part of and also the academic community of scientific and social scientific thinking. A new era of using research tools and approaches to retell history, rewrite the stereotypical story of the noble savage and forge a path that has yet to be explored by asking new questions is emerging. The picture of the indigenous person and the indigenous community is being interpreted and described increasingly from within the community as opposed to by someone from outside.

Responsibility

Given the damaging history of research within indigenous communities, a new research paradigm is required as we move forward. This is articulated in part in the context of the responsibility to stand up as indigenous and allied researchers and articulate the importance of research in meeting the needs of the community and answering questions of relevance to the community rather than those that fascinate the researcher. In this regard, there is a natural affinity with community-based research, Community-Based Participatory Research and action research, among other critical methodologies. The emphasis of these approaches, including the expectation that research must lead to change, resonates with indigenous community demands. Research for the sake of describing a situation, documenting the cultural practices of an indigenous population or developing an analysis of a community's context in isolation from community members/stakeholders and then publishing it is utterly and completely unacceptable.

Relationship Building

In 2005, Harris and Wasilewski wrote about the four Rs of research: (1) responsibility, (2) relationship,

(3) reciprocity and (4) redistribution. In the 2008 Canadian Aboriginal AIDS Network, Wise Practices II: Living Knowledge Aboriginal Community-Based HIV & AIDS Research & Capacity Building Conference, Jean-Paul Restoule introduced the five Rs of research: (1) respect, (2) reciprocity, (3) relevance, (4) responsibility and, in the Aboriginal context, (5) relationship. A researcher engaging with indigenous communities must fundamentally understand these concepts.

Without delving deeply into each of the Rs, the core message is that research with indigenous peoples and communities does not follow what might be understood as a more 'traditional' academic model. Controlling for bias by maintaining distance from the 'subjects' of the research and subject matter may compromise the quality of research when working within an indigenous context. Respectful research approaches demand that a researcher learn about the community, the history of the territory, the leadership, the needs of the community and the place(s) that the research might find to contribute towards meeting needs.

In parallel with community-based research, Community-Based Participatory Research and action research methodologies, the researcher must engage with the community. This occurs on the community's terms and within the community's time frame. Reciprocity dictates that something is exchanged when a request is made. This may mean volunteer work, attending community events, capacity building and/or participating in a ceremony. Research unfolds as the community is ready, and generally trying to dictate a strict timeline will result in incomplete or sub-optimal project results. Investing the time to build a relationship, to share oneself as a person who engages in research, will result in forging strong ties within a project team. The relationships will be long-standing, and as the relationships grow, there is greater opportunity to learn and develop respect for the traditions and customs of a specific community.

A New Way of Defining Research Relationships

Increasing interest and capacity related to the potential for research gained momentum in the Aboriginal community in Canada through the 1990s. This resulted in greater investment in defining the conditions for research which would serve to articulate a mechanism to implement the Rs and contribute to the implementation of meaningful research projects. The longitudinal First Nations Regional Health Survey (RHS) implemented across Canada with regional direction became a vehicle to voice guidelines for a new research relationship.

The Oka Crisis

The summer of 1990 represents a turning point in the relationship between First Nations, more broadly Aboriginal peoples, and the government of Canada. What started as a dispute over plans to expand a golf course and luxury condominiums on land identified by the local Mohawk Nation as traditional territory, including a burial ground, escalated to a stand-off between the Mohawks and their allies and the provincial police, the national police force and the military. Referred to as the Oka Crisis, the dispute unfolded between the town of Oka and the Mohawk community of Kanasatake. While violence was discouraged by the Mohawk elders, shots were exchanged at one point and one person died. The larger land dispute regarding the Mohawk claim to the contested territory has not been fully resolved as of 2012; however, the golf course development did not proceed. The Oka Crisis has come to represent a political turning point in the context of relations between the Aboriginal peoples and the Canadian government. The stance to protect traditional territory highlighted the importance of the broader protection of tradition as a whole. This also fuelled the dialogue regarding self-determination in all aspects of the research process and the articulation of First Nation rights within the research project.

OCAPTTM: Ownership, Control, Access and Possession

OCAPTTM emerged as a political response to the history of bad research within First Nation communities in Canada and echoes the experience of defending inherent First Nation rights in Oka. As one of the first articulations of the indigenous voice in the research process, it has been influential well beyond the boundaries of the First Nation community and has fuelled significant progress in the development of indigenous research protocols. Evolving from leaders' discussion regarding the RHS in the late 1990s, the term was first expressed as *OCA*; the *P* was added later. Academic papers about the principles of OCAPTTM were first written by Brian Schnarch. The concept, however, rests more explicitly with those involved with the RHS, the Canadian National Aboriginal Health Organization and the First Nations Information Governance Centre. The First Nations Information Governance Centre trademarked OCAP in 2010.

Brief explanations of the OCAPTTM terms are offered below.

Ownership

This asserts the collective ownership of a community over knowledge and information. Cultural traditions,

for instance, belong to all, and an individual does not 'own' this information or have authority to share it without communal consent.

Control

This underlines the right to equal voice and to exercising control over what occurs throughout the research process. Nothing moves forward without community consent—in other words, through review—and ongoing engagement on a research team to ensure that protocol is followed and respectful research practices are in place.

Access

This speaks to the right to have access to information that is gathered about the community and to decide who else is able to see this information. The principle does not imply access to private individuals' personal information but rather to the data set.

Possession

Physical possession of data is one of the most direct means to maintain control, manage access and assert ownership. When possible, research data and materials remain in the possession of the community. When the community is unable to securely maintain data, another institution takes on a stewardship role, physically holding the data and materials on behalf of the community.

As a set of principles, OCAP™ offers a mechanism for engaging in research with integrity. The expectations articulated above apply to all researchers, regardless of cultural background or belonging within the community where the research unfolds. Various tools, such as research team agreements, can be useful to concretely write down and reinforce where ownership rests, how control will be exercised, expectations regarding access and where research data will be stored. An agreement can further clarify how disagreements will be resolved—the OCAP™ principles, for instance, are not meant to silence team members but rather to ensure that all voices will be heard. Furthermore, working within an OCAP™ framework helps leverage opportunities for capacity building and forming a strong team. Not every team member can or should contribute equally to the research work load or have the same skill set. Instead, there is shared authority, oversight, influence, and decision-making based upon developing clear agreements that act as a bridge between community and academic language and customs.

OCAP™ explicitly emphasizes the voice of First Nations from the conception till the completion of the research process. It is most relevant and applicable in the context of geographically defined tribal

lands where leadership and protocols are explicitly defined. In urban settings too, the spirit and principles of OCAP™ remain relevant.

Ethics and Self-Determination in Research

Ethical guidelines regarding research with indigenous peoples internationally predated the articulation of the First Nation principles of OCAP™. Building upon statements such as OCAP™ in more recent years, increasing numbers of Nation- or community-specific research ethical reviews are required for undertaking research. Reflecting the interconnectedness within the indigenous community, ethical review is grounded in the value that the good of the whole serves the good of the individual.

In ethics review, the fundamental principle is analysis of a research plan to ensure that harm or risk of harm is limited for research participants. Indigenous experiences with research may expand the understanding of harm beyond the individual to the collective. The review questions who and what will be protected not only in the context of individual participants but also in the context of the local community and perhaps the Nation.

One might also ask whether there will be any benefit from the research and not just the risk of harm. Research that contributes towards community healing, empowerment, strategic development and sustainability is essential. This does not imply that research will focus only on investigations that might result in 'making a community or population look good'. There are many serious and devastating realities that demand a response and must be further understood. The priority is to undertake research with a mindset that respects the story that will be told as the research evolves, research that is mindful of the meaning and impact it will have in the community and beyond, and sets out to contribute meaningful new knowledge in response to the reality to support the potential for positive change.

Conclusion

Respectfully approaching research within the indigenous community fundamentally demands attention to history, politics and the right to self-determination. This is realized differently by indigenous peoples around the world. In principle, however, there are shared values and principles that ring true and are more or less consistent in the context of research *with* indigenous peoples rather than *on* indigenous peoples. The proceeding materials are offered from the perspective of one community-based researcher actively engaged in research in Canada. There are many other stories filled with humour, weighed down with the devastation of bad research and also celebrating the increasingly positive impact

of community-centred research. Discussion with local community members interested in research is highly encouraged to respectfully learn about local protocols for engagement.

Action research methodologies fundamentally resonate with expectations for community engagement and undertaking research that will enhance the community of interest. The potential for positive change is tangible. As we make the road by walking, this is one story along the path of good or 'wise practices' in research with indigenous peoples.

IRM has broadened its scope in recent years to include insights and principles borrowed from feminist, post-colonial and anti-racist research. In this respect, IRM is also a hybrid, a blend of existing research methodologies and methods that has been increasingly anchored within epistemologies, experiences, languages, cultures and spiritual traditions that are specifically indigenous (e.g. First Nations, Inuit and Metis in Canada; Māori in New Zealand; Aborigines in Australia, etc.). It is therefore important to realize that IRM is not, as some authors would have it, a methodology and methods for studying populations that are native or indigenous to a particular region but rather a heterogeneous set of methodologies and methods in the service of indigenous peoples aimed at comprehending, explicating and analyzing the contemporary world from their standpoint within it. Indigenous research methodologies and methods, therefore, invert the accepted or received social organization of the research process by allowing indigenous epistemologies and world views to define how and in what ways social research should be conducted according to protocols established by Aboriginal communities.

As IRM is a new and emerging methodology, it is also a contested conceptual and theoretical terrain. One effect of this is that IRM is used interchangeably, and often loosely, with terms such as *decolonizing methodologies* to denote any one of a range of disparate research approaches that focus on Aboriginal communities, issues and themes. This conceptual slippage is also applicable to the terms *indigenous*, *Aboriginal*, *First Nations* and so on, where there is no agreed-upon terminology. As such, therefore, there is no definitive or ideal model of IRM. Rather, there are versions of IRM across a broad spectrum of the research process. In this sense, IRM is probably best conceptualized as a continuum that encapsulates a wide range of research methodologies and methods that are concerned with indigenous epistemologies, ontology, voice and identity. This entry should, therefore, be read with these caveats in mind. This entry on IRM is organized into three sections: (1) history, themes and issues; (2) methodological considerations and (3) contemporary trajectories and critique.

History, Themes and Issues

IRM has its origins in the late 1990s and so represents a new and emerging field of inquiry within the social sciences that is still being defined. While it is widely considered that Linda Tuhiwai Smith's groundbreaking text, *Decolonizing Methodologies* (1999), marked the beginnings of a nascent IRM with its roots and inspiration in a Māori-centred cosmology, it is also clear that it has also drawn on (Western) intellectual

INDIGENOUS RESEARCH METHODS

Indigenous research methods (IRM) have only emerged within the Western academy in the early twenty-first century. Drawing initially, though not exclusively, on Participatory Action Research (PAR), Freirian critical pedagogy and non-positivist forms of qualitative research methodology for its impetus,

traditions for its inspiration and development. These have included feminism, PAR, forms of neo-Marxism, Freirian adult education theory and, particularly, critical pedagogy, as well as post-positivist approaches in qualitative research.

However, while Western intellectual traditions have been influential on IRM in its current form, particularly as increasing numbers of young Aboriginal people enter graduate school to conduct doctoral work, IRM can also be understood as emerging from at least three other developments over the past 10–15 years. First, as the title of Smith's book suggests, IRM has been closely allied with indigenous social and political struggles focusing on decolonizing the institutions imposed by colonial powers over the past 200 years (e.g. residential schools), as well as resisting contemporary neocolonial/neo-liberal forces aimed at commodifying their traditional lands through, for example, mining and forestry. Second, arising out of these struggles have been concerted efforts aimed at self-determination, ranging from asserting individual and collective rights and self-governance to creating public spaces in mainstream society for indigenous issues, concerns and rights to be addressed (e.g. Truth and Reconciliation Commissions). Third, and perhaps most important, has been the recognition that indigenous knowledge, customs, spirituality, traditional medicine and healing practices are deep reservoirs for constructing indigenous research methodologies that are autonomous of, and distinct from, existing Western research traditions.

Combined, these factors have contributed to an emerging self-awareness on the part of indigenous peoples that their ways of knowing and being are either neglected or marginalized within mainstream society and the academy. While some progress has been made over the past 10–15 years in establishing indigenous research programmes in universities and related post-16 institutions, it is nevertheless still the case that the core disciplines (medicine, science, engineering, humanities, social sciences, etc.) have made very little progress in acknowledging or incorporating Aboriginal world views into what they teach and research. Indeed, it is still probably the case that Aboriginal people are considered the 'objects' of research. One notable exception to this has been in the field of educational studies (and to some extent, social work), where academic programmes on indigenous education and research do appear to have made substantial advances in both admitting Aboriginal students and incorporating their experience and perspectives within curricular and research agendas. In 2010, for example, the Association of Canadian Deans of Education (ACDE) signed an Accord on Indigenous Education that had as its basis the following four principles: (1) to actively foster

a socially just society for indigenous peoples; (2) to acknowledge a respectful, collaborative and consultative process between indigenous and non-indigenous peoples; (3) to promote partnerships between educational institutions and indigenous communities and (4) to value the diversity of indigenous knowledges and learning. Recognizing the need for transformative educational change within the educational system, the accord goes on to outline the following goals: (a) creating respectful and welcoming learning environments, inclusive of curricula and culturally responsive pedagogies; (b) promoting and valuing indigenous identities; (c) conducting culturally sensitive assessments; (d) revitalizing indigenous languages; (e) asserting indigenous education leadership and (f) promoting indigenous research. It should be noted that the accord reflects a global trend in other countries too, particularly Australia and New Zealand, where faculties and colleges of education have been leaders in creating institutional spaces for indigenous educational programmes in research to develop and thrive. In New Zealand, for instance, Māori Wananga have established institutions (since 1989) of higher education operated on Māori language, curricula, teaching and learning practices. Canada's First Nations University (1976) is another example of this, where policy reform has created institutional space for Aboriginal scholars to explore, elaborate and apply research methodologies and methods founded on indigenous epistemologies. Similar policy and institutional reforms have also been implemented in Australia and the Nordic countries (e.g. concerning the Australian Aborigines and the Sami, respectively).

Principles and Practices

As noted earlier, although IRM has developed within the shadow of the mainstream social sciences and has been informed by their disciplinary thinking, it is also nevertheless the case that the ontological and epistemological foundations of indigenous everyday life, experience and history have generated the development of significantly different principles and practices regarding social research. The overarching consideration against which all IRM has to be contextualized is the history of colonization that most indigenous people have been subjected to over the past 500-plus years in North America and around the rest of the globe. Understood against this backdrop, IRM cannot be viewed as simply another technical contribution to the vast toolbox of qualitative methods that has emerged in the past four decades but as a determined political and ethical challenge to the continued marginalization of indigenous peoples within post-16 educational institutions. First and foremost, therefore, the principles and

practices that constitute IRM have to be understood as emerging from the essentially political nexus between decolonization and self-determination.

Flowing from this nexus, several principles and practices have come to shape and define IRM in recent years. All of these can be broadly understood as arising from an indigenous world view that emphasizes respect, relationship, reciprocity and the central place of the spiritual world in everyday life (both Aboriginal and non-Aboriginal). First, contemporary social theory and conceptual apparatuses have to be re-conceptualized through an indigenous lens. While this does not imply the outright dismissal of Western social theory as a product of colonial history, it does require researchers adopting IRM to systematically and critically engage with the underlying assumptions of Western social science from an indigenous standpoint. This is achieved not only at the level of method, where, for instance, emphasis is placed on collective knowledge-producing practices (e.g. conversation circles and storytelling) as opposed to the structured individual interview, but also through the recognition that the spiritual realm is expressed through the physical world (through dreams, rituals, elders) and needs to be valued and appreciated accordingly. In brief, everything has a life force and should be understood relationally. Second, the research process must be inclusive of indigenous communities and individuals. Ideally, this would include key elements such as design, implementation and report back, but it would also include training in research methods, such as data gathering, analysis and communicating of findings. Third, attention must be given to protecting specific aspects of indigenous knowledge, especially those connected with spirituality, traditional medicines and healing practices that are deemed to be sacred to a particular culture or people. In recent years, indigenous communities have established elaborate protocols on how research is to be conducted within their communities for this purpose. Fourth, indigenous voices, epistemologies and ways of being should be privileged. Fifth, within non-Aboriginal contexts, IRM can perform an activist function in allowing indigenous people and their collaborators to push for and open up spaces for dialogue, debate and education on issues of concern to indigenous people.

Overall, these principles and practices can be understood as defining the emerging field of IRM. It needs to be emphasized, however, that this is a new field of research and is in a state of flux and change, so some or all of the themes identified above may evolve and transform as the field develops over the coming decade.

Future Directions and Critique

As suggested above, IRM has a very short history within the academy, emerging only over the past 10–15

years, and it is still evolving. Also, apart from the field of educational studies, where it has a relatively strong and increasing profile, IRM has had relatively little or no impact on mainstream social science research in disciplines such as sociology or anthropology. While there is some evidence that this may be changing, it is nevertheless the case that some of the core principles on which IRM is grounded, such as the notion that the social/physical world is fundamentally shaped by the spiritual realm, are so antithetical to Western conceptions of science that any progress in this respect will likely be cautious, slow and tentative.

This is not to argue, however, that IRM will dwindle and fade in the coming years. On the contrary, there are signs that it may be embraced by researchers (both Aboriginal and non-Aboriginal) involved in professional and private consulting on issues connected with health, education and social services programming in Aboriginal communities. That said, the adoption and integration of IRM within research organized around this kind of research—usually in the form of programme evaluation—will not necessarily signal an advance for IRM or indigenous research *per se*. Rather, it is possible that it will mark the co-option of IRM by both private and state-organized interests for the purposes of opening up Aboriginal communities for the kinds of neocolonial (i.e. neo-liberal) development that IRM was originally created to critique, challenge and oppose. In this respect, IRM may suffer the same fate as forms of PAR that have been effectively de-radicalized and neutered by institutions such as the World Bank, International Monetary Fund and other international agencies through their poverty reduction programmes in the Global South. Notwithstanding, there are also equally strong contrary indications that IRM may also stay true to its anti-colonial roots and continue to be inspired by radical indigenous movements such as the Adivasi movement in India or the ‘Idle No More’ movement in Canada. The future of IRM will, therefore, hinge as much on the work of indigenous scholars and sympathetic colleagues within the academy as on the outcome of political struggles engaged in by indigenous communities and their allies for self-determination.

INFORMATION AND COMMUNICATIONS TECHNOLOGY AND ORGANIZATIONAL CHANGE

The effective introduction of modern information and communications technology (ICT) systems requires a highly co-ordinated and integrated approach to the management of both technological and organizational change. While much has been written about the need to attend to this challenge, it remains that a rather small proportion of change initiatives appears to address it in a manner that delivers successful business outcomes. Success is grounded in a well-honed ability to seamlessly co-ordinate and integrate multiple domains of organizational practice while simultaneously attending to organizational practitioners and their embedded practice orientations. In taking a close look at the need for effective co-ordination and integration, this entry illuminates the need to focus on the process of changing, with particular emphasis on the role of organizational practices and organizational practitioners in fostering integrated change.

Extant research over the past five decades unambiguously asserts that organizations intent on maximizing the business value of ICT can do so by attending to the challenge of change in a co-ordinated and integrated manner. While modern ICT systems offer unprecedented opportunities to transform both core and support business functions, such transformation is best progressed in an environment where both technological

change and organizational change are advanced simultaneously. The absence of such an environment contributes to the dominance of technological change at the expense of organizational change. Once dominant, a narrow agenda for technological change will marginalize and ignore the human and organizational aspects of change which are central to enhancing organizational performance. While the field of organization development can make a unique contribution in terms of addressing the human and organizational aspects of change, it is sobering to see how the ICT domain is replete with narratives of failure due to the dominance of narrow technological change agendas.

To advance a highly co-ordinated and integrated approach to both technological and organizational change, one must become immersed in the process of changing, with particular emphasis on organizational practice and organizational practitioners. While it is technically correct to draw attention to the need for co-ordination and integration and equally correct to note the propensity for marginalizing the human and organizational aspects of change, such correctness offers little by way of rich insight into the need to both inform and transform organizational practice and organizational practitioners if the process of changing is to effectively address the integration challenge. If co-ordination and integration are not advanced as part of the process of changing, they are unlikely to be attended to at all.

The Process of Changing

It is in the process of changing that one encounters the messy world of organizational practice as shaped by a myriad of organizational practitioners. Indeed, it is here that multiple and often competing theories of change are surfaced and expressed in the here-and-now actions of organizational practitioners. It is in following the process that one can establish how organizational practitioners co-ordinate and integrate both technological and organizational facets of change across multiple domains of organizational practice. In the event that technological change reigns supreme, an in-depth critique of the process of changing will undoubtedly reveal the hegemony of certain organizational practitioners and organizational practices. In essence, the process of changing always reveals the keys to effective co-ordination and integration if they are present.

Organizational Practices

While it is fitting to speak to the need for a highly co-ordinated and integrated approach to the management of both technological and organizational change, such co-ordination and integration are the fruit of well-honed organizational practices across multiple organizational

domains, including strategic diagnosis, planning change, intervention and evaluation. Each of these domains benefits from well-honed organizational practices that address both technological and organizational change in a highly co-ordinated and integrated manner. *Strategic diagnosis* addresses the integration of technology and organization when adapting to a changing business environment. *Planning change* deliberately attends to both technological and organizational change in pursuit of clear strategic outcomes. Effective *intervention* intentionally advances both social and technical interventions in a seamless manner. Effective *evaluation* assesses both social and technical outcomes in the full knowledge that integration is a product of multiple domains of organizational practice.

In essence then, the integration of ICT and organizational change warrants a keen eye on multiple domains of organizational practice. While each domain makes a unique contribution to the process of changing, it remains that integration must be addressed both within and across domains. Invariably, this places a high premium on integrating the different forms of knowledge, skill and expertise which underpin the respective domains. This challenge can become all the more exacting when one recognizes that each practice domain has its own organizational practitioners, with few having the requisite depth to navigate all domains.

Organizational Practitioners

Notwithstanding the challenges associated with multiple domains of organizational practice, the integration challenge with ICT becomes all the more demanding when one explores the range of organizational practitioners involved in the process of changing. *Strategic diagnosis* regularly involves executive management, professional staff and outside strategic advisors. *Planning change* frequently involves middle management and professional staff. *Intervention* involves organization development professionals and ICT professionals. *Evaluation* involves a range of internal and external audit and evaluation professionals. With so many groups of organizational practitioners involved in the process of changing, it is important to recognize that these groups do not naturally have a shared understanding of either the process of changing or the distinctive challenges involved in integrating ICT and organizational change. Effective collaboration within and across these groups in pursuit of integrated change regularly requires its own intervention strategy in the first instance.

The Appeal of Action Research

Fostering an environment that favours a co-ordinated and integrated approach to the management of change

regularly requires a multi-tiered intervention strategy. Action research has a central role to play in this regard. With its emancipatory and re-educative emphases, action research focuses on the myriad of organizational practitioners and their embedded practice routines with a view to uncovering dysfunctional patterns of practice that impede change while simultaneously nurturing functional patterns of practice that promote change. The effective use of action research here favours transforming practice which is essential to the realization of effective change outcomes.

INFORMATION SYSTEMS

Since the 1950s, the process of introducing information systems (IS) in large organizations has been marred by reports of persistent underperformance and failure. While it emerges that this is due, in no small part, to an inability to foster an integrated approach to change, it is unfortunate that much IS-related inquiry has failed to adequately address this dilemma. Acknowledging the weaknesses of dominant positivist research approaches, this entry outlines the case for action research as a legitimate and important post-positivist family of research approaches relevant to investigating this enduring dilemma with IS.

The Plight With IS

Empirical studies over the past five decades provide strong evidence to support the assertion that underperformance and failure frequently mar the introduction of IS in large organizations. Unfortunately, the number

of IS initiatives that actually deliver promised business value is in the order of 10 per cent, while the number of initiatives that fail or are abandoned completely is in the order of 50 per cent. The remaining 40 per cent of initiatives tend to be delivered late, over the budget and with significantly reduced functionality. The impermeable and enduring nature of this dilemma is of concern to organizational researchers and practitioners alike.

Such underperformance and failure are rarely explained by way of attending to economic and technical considerations alone, yet such criteria appear to dominate the introduction of IS in organizations. Executive management tend to view the introduction of IS as an economic imperative, while IS management tend to view it as a technical imperative. Alas, this narrow techno-economic bias, sustained over time by the coalescent behavioural patterns of the executive and IS communities, results in the human and organizational aspects of IS initiatives being marginalized and ignored.

Such an outcome is rarely inconsequential since failing to attend to the human and organizational aspects of change is said to be responsible for the high incidence of underperformance and failure. Indeed, researchers are increasingly of the opinion that the economic and technical aspects of IS account for less than 10 per cent of the underperformance and failure, while human and organizational factors account for more than 90 per cent. The nature of this dilemma is both obstinate and enduring.

This predicament is further compounded by an inability to effect integrated change due to the requisite knowledge, skill and expertise being widely dispersed in organizational settings. Organizational researchers and practitioners who understand the technology tend to have little appreciation for the human and organizational aspects of IS. Similarly, organizational researchers and practitioners who understand the human and organizational aspects of IS tend to have little appreciation for the range of increasingly complex technologies that underpin modern IS initiatives. Addressing this plight inevitably places a high premium on integrating different forms of knowledge, skill and expertise.

The Appeal of Action Research

Reflecting on the weaknesses in the dominant approaches to IS-related research and the associated enduring plight with IS, it appears that action research offers an unrivalled opportunity to develop a more holistic approach to inquiry. This assertion is based upon a number of important postulates.

Action research provides a legitimate basis for embracing the concerns of researchers and practitioners alike. Both the practitioner and the researcher are

concerned with the immediacy of a particular problematic or challenging situation and are equally focused and committed to effective social action with a view to effecting change. By wholeheartedly embracing the world of the practitioner, the researcher develops deep insights that provide a sound basis for the development of robust social theory. Action research, therefore, redresses the perceived lack of relevance in much extant research. When investigating the role of executive management in IS-related initiatives, action research facilitates the integration of the organization's need to foster an integrated approach to change and the researcher's need to establish how executive management shape IS initiatives.

Action research is capable of embracing the dynamic and developmental nature of IS initiatives. This is of particular importance since much extant research is excessively static, with some authors noting that static, one-shot, cross-sectional studies are clearly the predominant form of research in the IS field. Cross-sectional studies fail to capture the dynamic and developmental nature of change and also fail to account for the actions, reactions and interactions of key social actors that shape the processes of change. Action research's collaborative approach to inquiry and change redresses this plight by attending to both the developmental nature of change and its sociopolitical context. When investigating the role of executive management in IS-related initiatives, action research fosters a longitudinal perspective on change wherein the dynamic and developmental processes of change remain central themes of concern to the researcher.

With its processual focus, action research is capable of facilitating the integration of the diverse forms of knowledge and expertise that executive management use to shape the introduction of IS in organizations. Action researchers proactively embrace the distinctive perspectives on IS as embraced by executive management. Action researchers' knowledge of strategy, change and IS enables them to embrace the multifaceted nature of executive behaviour in the context of IS initiatives. When investigating the role of executive management in IS-related business change, action research facilitates the integration of diverse forms of knowledge and expertise, which underpin the diverse roles of executive management in large-scale change programmes.

Action research is capable of facilitating the integration of the diverse requirements and demands that executive management place on the process of introducing IS. In particular, action researchers are capable of crafting a more integrated approach to the introduction of IS that accommodates the diverse demands of executive management, which result in the need to concurrently embrace strategic, technical, social and

political perspectives on IS initiatives. The action research process enables the development of a shared dialogue among executive management. When investigating the role of executive management in IS-related business change, action research facilitates the integration of the diverse requirements and demands embedded in the diverse roles of executive management in large-scale change programmes.

Action research is capable of reconciling the diverse bases of power and influences that executive management use to shape the introduction of IS. Action researchers embrace the role of negotiator when addressing this distinctive challenge. Inevitably, this may involve a significant compromise since addressing the collective requirements and demands of executive management may not be feasible when all known constraints on change are accounted for. Action researchers rightfully recognize the diverse bases of power and influence and seek to negotiate a way forward that is acceptable to all executives. Action researchers do not take sides between conflicting groups; rather, they build a trusting relationship with all parties so that they can act as brokers of inquiry, co-operation and compromise. When investigating the role of executive management in IS-related business change, action research reconciles reward and coercive power, technical expert power, affiliative power and referent power.

Action research is capable of uncovering, challenging and changing the polarized patterns of cognition and action with respect to IS embodied in the executive and IS communities. The importance of explicating the implicit theories which guide informed human action with respect to IS is of the utmost importance when one considers the unintended consequence of the economic and technical mindsets of the executive and IS communities, respectively. As has been previously argued, the coalescent nature of these mindsets is such that the human and organizational aspects of IS are frequently marginalized and ignored. Considering the embedded nature of the executive and IS mindsets with respect to IS, the effective introduction of IS necessitates real-time re-education for both communities. Action research wholeheartedly embraces this re-educative agenda as part of the investigative process, as demonstrated in multiple studies of executive management and IS-related business change.

Action research is capable of nurturing a collaborative approach to change based on the principles of partnership and participation. Recognizing the rightful place of diverse forms of knowledge and expertise along with diverse requirements and demands, action researchers proactively cultivate a collaborative approach to change that accommodates the political realities of organizational life. Indeed, this is accomplished in a manner that attends to the introduction of

IS in an integrated manner, concurrently attending to strategic, technical, social and political considerations. It has been well established that when investigating the role of executive management in shaping IS-related business change, action research nurtures a collaborative approach to change, particularly within the executive suite.

A Paucity of Action

Notwithstanding the increased advocacy for and significant appeal of action research, how prevalent is this research strategy in the IS literature? Unfortunately, while there is strong evidence that action research is growing in importance within the IS academic literature, it remains a peripheral rather than a mainstream research strategy. In so far as growth is discernible, it is being facilitated by a range of academic journals that see action research as a legitimate and valuable research strategy within the IS domain.

In a recent review of the top 10 IS academic journals between the period 1982 and 2005, Mike Chiasson and his colleagues found that only 63 published papers utilized action research as part of the research strategy. That accounts for 1.57 per cent of all published papers. Of the 63 papers identified, only 25 used action research as the dominant research strategy, while the remaining 38 used it as a complementary research strategy considered helpful for additional examination and explanation of the research phenomenon as the research programme unfolded. That accounts for 0.62 and 0.94 per cent of all published papers, respectively.

Most academic papers utilizing an action research strategy are published in only a handful of academic journals. Of the 63 papers noted above, 51 have been published in *Information Systems and People*, *Information Systems Journal*, *MIS Quarterly*, *European Journal of Information Systems* and *Information and Organization*. The remaining 12 papers are scattered across a range of IS journals, including *Database*, *Information and Management*, *Journal of Management Information Systems*, *Information Systems Research* and *Journal of the Association for Information Systems*.

While the paucity of action research may be attributable to the dominance of positivist approaches to inquiry in academic research, there may well be a number of other caveats which limit the viability of action research as a preferred approach to inquiry and change. A quick perusal of extant research published in the IS academic literature suggests that action research has been associated with what might be best considered as limited interventions or small-scale change initiatives. Considering that the deployment of modern IS initiatives is frequently associated with the management of

large-scale organizational and technological change, it seems that the inherent value of action research in this regard is yet to be established. Moreover, as such large-scale change initiatives regularly make extensive use of multidisciplinary teams that span multiple domains of organizational practice, the strengths and limitations of an action research paradigm in this context are yet to be made explicit.

Conclusion

This increased emphasis on the appropriateness of action research for the study of IS in organizations is discernible. Notwithstanding such advocacy, unfortunately, despite its overwhelming acceptance in organization development, it is virtually non-existent in North American IS research. While action research is generally viewed in a more favourable light in Europe and Australia, it remains a peripheral research strategy even in these regions.

How is it that a family of research approaches which holds such promise is embraced by so few? Action research can address complex real-life problems and the immediate concerns of organizational practitioners. Yet, paradoxically, the academic IS community has almost totally ignored action research.

or community system in order to change something in it, they can be understood as undertaking insider action research. Complete membership is contrasted with those who enter a system temporarily for the sake of conducting research. It may be defined in terms of wanting to remain a member within a desired career path when the research is completed. Insider action research offers a unique perspective on systems, precisely because it is from the inside. The context of insider action research is the strategic and operational setting that organizational members confront in their working lives. Issues of organizational concern such as systems improvement, organizational learning, the management of change and so on are suitable subjects for insider action research since (a) they are real events which must be managed in real time, (b) they provide opportunities for both effective action and learning and (c) they can contribute to the development of theory for what really goes on in organizations. Insider action research is commonly undertaken by practitioners who are enrolled in practitioner programmes, such as executive masters or doctorates, M.B.A.s and part-time master's or undergraduate programmes. What is common across such programmes is that participants undertake some sort of project in their own organizational or community system, write it up and submit it as an extended essay or dissertation. When this project involves taking action or leading change, then insider action research is an appropriate way of framing it and writing about it. This entry identifies the main challenges for insider action researchers, (a) access, (b) pre-understanding, (c) role duality and (d) organizational politics, and discusses the key elements of these challenges.

Traditionally, there has been a general neglect of insider action research because it is typically based on two traditional assumptions: (1) that being native is inimical to good research and (2) that researching in action does not provide sufficient methodological rigour for generating valid knowledge. Being native in itself is not a barrier to good research. The development of approaches that are grounded in insider perspectives and of specific approaches such as autoethnography and self-ethnography provides evidence that the pejorative 'native' tag can no longer be sustained as inimical to good research.

The Challenges of Insider Action Research

Insider action research can be seen to involve the managing of four interlocking challenges. Firstly, insider action researchers need to gain *access* to be allowed to conduct the action research project. Secondly, they need to build on the closeness that they have with the setting while, at the same time, creating distance from

INSIDER ACTION RESEARCH

When complete members of an organization seek to inquire into the working of their own organizational

it in order to see things critically and enable change to happen. This is referred to as *pre-understanding*. Thirdly, they have to hold *dual roles*, their organizational member role(s) and the action researcher role, and deal with the consequent ambiguities and conflicts that can arise between them. Finally, they also have to manage *organizational politics* and balance the requirements of their future career plans with the requirements for the success and quality of their action research. Each of these four challenges makes demands on the processes of action and inquiry, and accordingly, attention to them and skill in managing them are integral to the inquiry and action practices of the insider action researcher. Action research is a dynamic process where the situation changes as a consequence of deliberate action. Action researchers have to deal with emergent processes, not as distractions but as central to the research process. Kurt Lewin's often cited maxim that one only understands a system when one tries to change it is illustrative of the development of pre-understanding that occurs in the course of an insider action research project. Similarly, in the emergent nature of the shifting situation in a system's change process, how the insider action researchers hold their dual roles and survive and thrive politically are challenges that need constant renegotiation.

Access

As insider action researchers are already members of the organization, they have primary access. While they have primary access, they may or may not have secondary access—that is, they may or may not have access to specific parts of the organization which are relevant to their research. By parts of the organization is meant not only functional areas such as departments but also hierarchical areas whereby there is restricted access to specific privileged information, which may not be available otherwise. Insider researchers may find, however, that membership of the organization means that some avenues are closed to them because of their position in the organization. Any researcher's status in the organization has an impact on access. Access at one level may automatically lead to limits or access at other levels. The higher the status of insider action researchers, the more access they have or the more networks they can access, particularly downwards through the hierarchy. Being in a high hierarchical position, however, may exclude access to many informal and grapevine networks. Fundamentally, secondary access means access to documentation, data, people and meetings.

An important aspect of negotiating the insider action research project is to assess the degree of secondary access which one is allowed. Of course, what is espoused at the outset and what is actually allowed

may be different once the project is under way and at a critical stage. There may be a significant gap between the aspiration towards 'purity' of research and the reality. How access is realized may depend on the type of research being undertaken and the way information is disseminated.

Negotiating access with superiors is a tricky business, particularly if the research project aims at good work and not something bland. It raises questions about the different needs which must be satisfied through the project. Insider action researchers have needs around doing a solid piece of research which will contribute to their own career and development and needs around doing a piece of research in the organization which will be of benefit to the organization and contribute to general theory for the broader academic community. Balancing these three audiences is difficult. In general, researchers' superiors have needs around confidentiality, sensitivity to others and organizational politics.

For insider action researchers who are undertaking the action research as part of a degree programme or who seek to publish, a particular issue relating to access is the fact that what is researched will be going outside the organization. Theses and dissertations are read by people external to the organization and are filed in libraries, with their abstracts disseminated to a wider audience. Articles may be published, and there are challenges in hiding the identity of the organization if the organization does not wish to be identified. These issues of access are embedded in the challenges of role duality and organizational politics.

Pre-Understanding

Pre-understanding refers to things such as people's knowledge, insights and experience before they engage in a research programme. The knowledge, insights and experience of insider researchers apply not only to a theoretical understanding of organizational dynamics but also to the lived experience of their own organization. Personal experience and knowledge of their own system and job are a distinctive pre-understanding for insider researchers. Insider researchers are part of their organizational culture, and therefore, there is much that they don't see, and they may find it difficult to stand back from it in order to assess and critique it. Their perspective may be partial as their experience may be based in one functional area of the system, and so they lack understanding of other areas. Their professional background may give them membership of one occupational community, and so they may lack understanding of other occupational communities. They need to be in tune with their own feelings as an organizational member—where their feelings of goodwill are directed, where their frustrations are and so on.

Closeness or familiarity has a tendency to inhibit inquiry. When action researchers are in new situations, they are conscious of what they do not know, and they work hard at figuring out what's going on and how to respond. In insider situations, action researchers are meeting the same people whom they meet every day. They engage in the same organizational rituals where they attend meetings with the same people and discuss the same topics that they had discussed previously. Accordingly, the key task of pre-understanding is to develop a spirit of inquiry in familiar situations where things are likely to be taken for granted, and the skills required are those of introspection, whereby the insider researcher's own assumptions are exposed to questioning and self-awareness and reflection skills are built. In short, pre-understanding for insider action researchers involves building on closeness and achieving distance.

Role Duality: Organizational and Researcher Roles

Augmenting one's normal organizational membership roles with the research enterprise can be difficult and awkward for insider action researchers. Within their organizational roles, they are managing within the boundaries of formal hierarchical and functional roles and the informal roles of collegiality and possible friendship and having a desire to influence and change the organization. Insider action researchers have to deal with the role expectations and 'sent-role' (the role they have been assigned) of the members of the system in which they are working. The system may not have unified expectations of the action research project, and so there may be ambiguities and conflicts as different members or factions hold different expectations of what role the action researchers are to play. At the same time, action researchers may have expectations of what their role is or what they want it to be, which may or may not accord with the role as understood in the system and its constituent factions.

As a result, insider action researchers are likely to encounter role conflict in trying to sustain a full organizational membership role and the research perspective simultaneously. Their organizational role may demand total involvement and active commitment, while the research role may demand a more detached, reflective and theoretical position. This conflict may lead to an experience of role detachment, where insider action researchers begin to feel as outsiders in both roles.

Organizational Politics

Organizations are social systems. As such, political dynamics are an integral part of organizational life. Any form of action and clearly any form of research in organization has its political dynamics. Political forces

can undermine research endeavours and block planned change. Gaining access, using data and disseminating and publishing reports are intensely political acts. Insider action researchers need to be politically astute. The term *political entrepreneur* is useful in this regard as it implies a behavioural repertoire of political strategies and tactics and a reflective, self-critical perspective on how those political behaviours may be deployed. Political entrepreneurship requires the ability to achieve congruence with one's value set and the value set of action research and to find ways to exploit learning opportunities within the organization. Insiders have a pre-understanding of the organization's power structures and politics and are able to work in ways that are in keeping with the political conditions without compromising the project or their own career. Learning to act politically in a mode within the values of action research is a core skill for insider action researchers. Working through the issues of value congruence is a challenging but required task. The process allows the individual to develop new personal capabilities that are critical for his or her own role and performance as an organization member and as an insider action researcher.

Many of the action modalities or forms of action research may be used in insider action research. Insider action researchers may frame their projects in terms of Action Learning, Appreciative Inquiry, Clinical Inquiry or Learning History, for example. They may utilize Action Learning sets or Co-Operative Inquiry groups as a structure for collaborative inquiry and action with their team or project group. They may draw on Action Science and Collaborative Developmental Action Inquiry as modes of reflective practice.

INSTITUTE OF DEVELOPMENT STUDIES

The Institute of Development Studies (IDS) is an independent research charity that is based at the University of Sussex in the UK. Created in 1965, it was one of the first global centres for work on international development. IDS positions itself as neither an academic organization nor a think tank but a multi-stranded organization that lies at the interface between scholarly thinking, practice and policy development, teaching and knowledge production.

Action research within IDS has its roots in the work of Robert Chambers, who continues to work on the Participation Power and Social Change team. Chambers was one of the pioneers of participatory international development, developing methodologies such as rapid rural appraisal and Participatory Rural Appraisal—approaches which have much in common with action research. His more recent work on community-led total sanitation has used Action Learning as an underpinning.

Over the years, IDS has built innovative action research programmes using a range of different methods. Examples include reflective practice and power analysis with NGOs (Jethro Pettit); action research programmes with young pastoralists (Patta Scott Villiers); action research using visual methods, including both Digital Storytelling and participatory video (Joanna Wheeler and Tessa Lewin); systemic action research (Danny Burns) and action research on climate change with community radio stations (Blane Harvey).

Another major foundation stone of action research at IDS was the ‘capacity collective’. Initiated in 2007 by Peter Taylor and developed by Peter Clarke and Katy Oswald, it brought together a group of practitioners to develop five action research initiatives in Nicaragua, Ecuador and Peru. These explored how Participatory Action Research could support processes of organizational and community capacity development and led to a series of publications, including ‘Reflecting Collectively on Capacities for Change’, in the *IDS Bulletin* in 2010. The lessons from the capacity collective have since been used in work with several other organizations that are undertaking action research to support processes of capacity development and learning. This has included work with SNV (The Netherlands Development Organisation) on systemic change, Care on Governance, the World Food Programme on gender mainstreaming and VSO (Voluntary Service Overseas) on the impact of volunteering on poverty.

Long-term links to influential thinkers and practitioners such as Rajesh Tandon, the director of PRIA (Participatory Research in Asia) and a board member

of IDS, illustrate the network connections between the wider participatory research movement and the action research process.

IDS runs a master’s programme in participation, power and social change. This is structured around a core piece of action research and is underpinned by training on research methods in action research. Action research offers a way of looking at the world and a set of tools which are congruent with a participatory world view, thus the imperative to embed it into the methodological fabric of the pedagogy. IDS also supports a growing number of action research Ph.D.s.

INSTITUTIONAL REVIEW BOARD

The charge of an Institutional Review Board (IRB) is to ensure that the rights and welfare of human research participants are protected. IRBs in the USA adhere to the federal human subjects regulations, known as 45CFR46, subpart A, or the Common Rule. These regulations include key definitions, rules and specific requirements regarding committee composition and authority. The Common Rule builds off the Belmont Report, which articulated the three guiding ethical principles of conducting research with human participants: respect for persons, beneficence and justice.

Action-oriented researchers must submit their research materials to an IRB if their project meets the Common Rule’s definition of research involving human participants and if anyone on the research team is affiliated with an institution or organization that requires an IRB review (e.g. an university). Additionally, certain funding sources and journal editors require IRB approval. Some action-oriented researchers critique the IRB process for its biomedical orientation and emphasis on individual-level considerations. This entry provides a brief historical overview of the human

subjects regulations and the IRB process, an overview of frequently cited critiques of the IRB process and recommendations on how to address these critiques.

Historical Overview of Research Regulations

Due to space limitations, this overview touches upon only the Nuremberg Trials, the Public Health Service (PHS) policy for extramural projects, the Belmont Report and the Common Rule. For a more comprehensive historical review, the reader is directed to the list of further readings at the end of this section.

Nuremberg Trials 1947

The first formalized international code of ethics was written after World War II during the Nuremberg Trials of 23 Nazi investigators. The trials focused on the Nazi ‘research’ atrocities conducted in the concentration camps, such as the infamous hypothermia experiments. The charge of the prosecutors was to distinguish between the Nazi activities and US wartime research. An established code of ethics was not available to guide the prosecutors. In fact, the American Medical Association produced a code of ethics only during the trial, partly in response to the trial proceedings.

The Nuremberg Code was initially drafted by physicians and later revised by the US Counsel for War Crimes. The Nuremberg Code was designed to regulate medical experiments. The code consisted of 10 ‘basic principles’, which addressed issues such as informed voluntary consent, risk assessment and the need for scientifically qualified experimenters. Although there was stringency in the language used, the Nuremberg Code did not mention the need for external review boards.

PHS 1966

Prior to the 1960s, the general public had high levels of trust in the efficacy of biomedical research. This trust, however, began to disintegrate, in part as a result of foetal abnormalities caused by thalidomide. In response, Congress passed the US Food and Drug Administration’s Kefauver-Harris amendments to the Federal Food, Drug, and Cosmetic Act, which looked at issues such as the safety and efficacy of medical trials and informed consent. At this time the National Institutes of Health (NIH) also commissioned a study that found that few institutions had human participants review the policies in place, while other institutions that had policies were not adhering to them.

The PHS policy for extramural projects (PHS 1966) attempted to increase institutional accountability for the conduct of research with human participants. PHS 1966 required independent review of research protocols, although it offered minimal guidance on how a

review should occur. If researchers failed to comply, NIH could withhold funds. At this time, the NIH Division of Research Grants became the NIH Office for Protection From Research Risks (which has since moved out of NIH to the Department of Health and Human Services, becoming the Office for Human Research Protections).

National Research Act 1974

Recommendations from the Tuskegee Syphilis Ad Hoc Panel and public outcry contributed to the passage of the National Research Act in 1974. For readers unfamiliar with the Public Health–sponsored syphilis study, this 40-year study failed to demonstrate respect, caused significant harm to individuals and the broader community and was an injustice. Two key outcomes of the National Research Act were the requirement that all research receiving federal dollars undergo an IRB review, and the Belmont Report (1979). The Belmont Report named three guiding ethical principles and outlined how these were to be applied in an ethics review. The Belmont Report authors acknowledged that other ethical considerations may be relevant but that these three principles were ‘comprehensive’. The three principles, their meaning (verbatim from the Belmont Report) and their application are listed below:

- *Respect for persons*: ‘Respect for Persons requires that subjects, to the degree that they are capable, be given the opportunity to choose what shall or shall not happen to them’. This principle informs the requirements pertaining to informed consent.
- *Beneficence*: ‘Do not harm and maximize possible benefits and minimize possible harms’. This principle informs how the IRB conducts its risk/benefit analysis.
- *Justice*: ‘Who ought to receive the benefits of research and bear its burdens?’ This principle informs the assessment of sample selection.

The Belmont Report’s stated purpose was the development of an ‘analytical framework that will guide the resolution of ethical problems arising from research involving human subjects’.

The Common Rule of 1991

As part of the recommendations from the Presidential Commission for the Study of Ethical Problems in Medicine and Biomedical Research, the Federal Policy for the Protection of Human Subjects was published in 1991. This federal policy, referred to as 45CFR46, subpart A, or the Common Rule, was informed by the Belmont Report. Critiques of the

Common Rule, however, suggest that the Belmont Report's framework is overshadowed by its emphasis on procedural considerations.

The Common Rule provides key definitions, including what constitutes 'research' and 'human subjects', as well as rules and procedures governing the ethics review process. The Common Rule includes sections on committee composition and criteria for IRB approval. More specifically, the Common Rule, with regard to membership, states,

The IRB shall be sufficiently qualified through the experience and expertise of its members, and the diversity of the members, including consideration of race, gender, and cultural backgrounds and sensitivity to such issues as community attitudes, to promote respect for its advice and counsel in safeguarding the rights and welfare of human subjects.

Additionally, the Common Rule requires a membership composed of at least five individuals, including one non-affiliated person, one non-scientific person and one scientific person. These committee members should not be of the same gender or profession. The Common Rule further suggests that the committee consider inviting an additional non-voting member in instances where the committee does not have the requisite expertise.

At an IRB review meeting, a quorum of reviewers must be present to determine whether the proposed research is to be rejected, accepted or accepted with contingencies. An exception to this requirement is when the proposed research meets the criteria for an expedited review, which involves no more than minimal risk. An expedited review does not require a full-committee review, and it may be assigned to select reviewers based upon areas of expertise.

With regard to criteria for approval, the Common Rule lists seven requirements. These criteria focus on issues of informed consent, risk assessment, sample selection, privacy and data monitoring. An example of a requirement that might pose concerns for action researchers is listed below.

Risks to subjects are reasonable in relation to anticipated benefits, if any, to subjects, and the importance of the knowledge that may reasonably be expected to result. In evaluating risks and benefits, the IRB should consider only those risks and benefits that may result from the research (as distinguished from risks and benefits of therapies subjects would receive even if not participating in the research). The IRB should not consider the possible long-range effects of applying the knowledge gained in the research (e.g. the possible effects of the research on public policy) as among those research risks that fall within the purview of its responsibility.

Another section of the Common Rule provides information related to the suspension and termination of IRB approval when researchers violate IRB requirements or their study results in significant harm. Other subparts contain information related to IRB registration and research involving 'vulnerable groups' (i.e. pregnant women, human fetuses, neonates, prisoners and children).

Critiques of the IRB Process

Some action-oriented researchers have expressed concerns with the IRB process, which includes concerns related to the regulations as well as how IRB reviewers implement the requirements. Critiques include the fact that the IRB process and the guiding regulations have an overly biomedical orientation and focus on individual-level considerations. This may result in problematic assumptions regarding how research is conducted. More specifically, due to a lack of familiarity with the methodology, reviewers may question action researchers' designs due to their applying research assumptions more applicable to clinical research.

Other concerns voiced in the literature touch on whether the guiding Belmont principles are adequate in scope, or conceptualized in a manner consistent with the values of action researchers. For example, does the Belmont Report's conceptualization of justice account for the social change commitments of action research? Rather than the distributive justice orientation of the Belmont Report, action researchers may speak more in terms of relational or social justice. Challenges may also surface with how the Belmont Report suggests that the IRB apply these principles. For example, with regard to the conduct of the risk/benefit assessment, the Belmont Report states, 'For the investigator, it is a means to examine whether the proposed research is properly designed. For a review committee, it is a method for determining whether risks that will be presented to subjects are justified. For prospective subjects, the assessment will assist the determination whether or not to participate'. Action researchers may see their role extend beyond a focus on the research design, to include considerations of the short- and long-term risks at both the community and the individual level. Further hindering the ability to conduct a thorough risk/benefit analysis, action researchers may question the Common Rule's position regarding the extent to which 'possible long-range effects' may be considered by the IRB. Typically, action researchers are committed to translating findings into action steps that help address the issue being researched.

Action researchers may also challenge the idea that the IRB alone is capable of understanding what constitutes a risk, particularly when there are concerns related

to the composition of the committee. The regulations specify that there must be at least one non-affiliated member. Questions arise as to what extent the non-affiliated individual and others on the IRB adequately understand community-level questions and concerns. Without an understanding of the community and the cultural context, the question emerges as to whether the IRB can adequately consider the overall ethics of a proposed project.

Additional concerns regarding the IRB process are discussed in some of the listed further readings at the end of this section.

Recommendations

Recommendations to address the concerns outlined above include the following: (a) adding a fourth guiding ethical principle focused on community, (b) developing additional questions for IRB applications that demonstrate the value of thinking about community considerations, (c) examining committee composition to increase the likelihood that some of the reviewers are familiar with action-oriented research as well as being attuned to the community context, (d) partnering with community-based research ethics review processes and (e) working with your IRB. The first two recommendations could help prompt IRB reviewers to broaden their scope of ethical analysis by examining issues such as community impact. More specifically, how might the proposed research benefit as well as harm the community? What strategies exist to ensure that research findings are shared within the community, and what steps have been identified to help translate the findings into action? With regard to the fourth suggestion, community review processes can provide invaluable insight into ethical considerations relevant to the involved community, which oftentimes are not routinely assessed by institution-based IRBs. The structure of these community review processes varies, to include some federally recognized IRBs and some community research advisory boards. The final recommendation points to the importance of working with one's IRB to develop a mutual understanding of the requirements and concerns in order to best move forward in achieving the shared goal of ensuring ethical research.

INTEGRATING GROUNDED THEORY

Although Grounded Theory and action research are distinct approaches, they have been effectively integrated by action researchers, who recognized their compatibility and their respective strengths and limitations. This entry explains the logic for integrating Grounded Theory and action research, highlights the benefits and challenges of this integration and describes three main approaches for bringing them together. The first approach uses Grounded Theory in action research to add rigour to the data analysis and theory construction, the second approach integrates Grounded Theory and action research sequentially to maximize the benefits associated with their exclusive use and the third approach calls for flexible reciprocal borrowing of methods, techniques and skills between action research and Grounded Theory.

The Logic for Integrating Grounded Theory and Action Research and Potential Challenges

Steinar Kvale's distinction between craftsmanship, communicative and pragmatic validity captures the benefits of integrating action research and Grounded

Theory. Communicative validity refers to testing the validity of knowledge through a dialogue, pragmatic validity considers the relevance of the knowledge for action and change and craftsmanship validity focuses on the quality of the research. While action research claims that the first two types of validity are strong, it has been criticized for lacking rigour. Thus, Grounded Theory's main attraction for action researchers is the credibility that comes with its well-regarded data analysis and theory development processes. Similarly, action research has well-developed participatory processes, and its orientation towards developing relevant knowledge can complement the relatively weak communicative and pragmatic validity of Grounded Theory.

This integration is possible as both approaches view theory development as an emergent process and rely on deductive and inductive thinking. In Grounded Theory, this thinking is the responsibility of the researcher, and while the process may include checking the interpretation of data with participants, it is not as participatory as in action research. Participatory processes, as well as practical requirements and local considerations, may constrain the scope of theory development in action research and limit it to the substantive level. However, as the work of Latha Poonamallee demonstrates, the integration of Grounded Theory and action research can facilitate the development of both substantive and formal theories. Similarly, although Grounded Theory is not essentially about action, the substantive theories generated by Grounded Theory can have practical utility and can provide direction for action and change.

With these considerations in mind, three main ways for integrating Grounded Theory and action research have been developed.

Applications

Integrating Grounded Theory Into Action Research to Enhance the Rigour of Theory Development

Using Grounded Theory to enhance the rigour of data analysis and theory development is the most common integration of Grounded Theory with action research. Richard Baskerville and Jan Pries-Heje refer to this approach as 'grounded action research' and provide a detailed account of its use in action research related to the practicality of a user interface management system tool. While highlighting the selective use of particular Grounded Theory coding strategies, memos and diagrams to structure the data analysis and theory formation, these researchers note that it is not possible to use Grounded Theory within action research as a comprehensive research method.

For example, it is difficult to adhere to Grounded Theory's principle of grounding theory in data as some categories in action research may be predefined when the study is initiated. In this form of integration, Grounded Theory can be used at any stage of action research.

Sequential Integration of Grounded Theory and Action Research

In sequential integration, Grounded Theory and action research are applied one at a time in a multiphase study. This separation facilitates the materialization of the full potential of each approach, without the constraints and requirements of the other. Adhering exclusively to the philosophy, principles and procedures of both approaches is particularly important when participation, credibility and action are equally important and when the subject matter is controversial. Candice Schachter, Carol Stalker and Eli Teram followed this logic in a project designed to develop sensitive practice guidelines for health professionals working with survivors of childhood sexual abuse. In the first phase of the study, they used interviews to develop Grounded Theory about the experiences of survivors in the health-care system and the survivors' perception of sensitive practice. This knowledge was used in two subsequent action research phases to develop a *Handbook for Sensitive Practice*.

Flexible Borrowing Between Grounded Theory and Action Research

Following the logic of the constant comparative method, Bob Dick integrated Grounded Theory thinking in action research without the tedious process of coding. In this approach, the constant comparison is made in structured discussions with individuals or small groups. The theory of action emerges by comparing and discussing agreements and disagreements, with constant probing for exceptions to agreements, and seeking explanations to disagreements. This approach was used effectively with *convergent interviews*, and its application is expanding to group processes. Combined with other action research methods, this dialectic process provides an efficient and flexible way for integrating theory and action. As such, it may also appeal to some grounded theorists.

The above three approaches are driven by the belief that the integration of Grounded Theory and action research can strengthen the craftsmanship and communicative and pragmatic validity of research. With this shared assumption, they offer a wide range of options for balancing rigour, participation, action and practical considerations. Considering the purpose of the

contemplated integration, researchers can decide which approach can most effectively address their need.

INTERACTIVE RESEARCH

Interactive Research is a term used for action research in Scandinavian countries, particularly Sweden. Just as action research takes many forms, so does Interactive Research; and often, the terms *Interactive Research* and *action research* are used interchangeably. The term was originally coined by Professor Lenart Svensson, an academic with a particular interest in workplace learning and a former research leader at the now defunct Swedish Institute for Working Life. The use of this terminology in part derives from the history of action research within each of the Scandinavian countries, particularly its positioning vis-à-vis the universities within each of the countries. It also reflects the uneasy nature of the power relationships between labour and capital in the workplace in which action research was originally introduced and encouraged. However, the terminology also reflects an attempt to put learning and dialogue at the centre of the research process. Thus, Interactive Research is seen as a research process characterized by joint learning by participants through their involvement in that process from the start. In this, therefore, it has much in common with Participatory Action Research.

The Context of Interactive Research: A Brief History of Action Research in Scandinavia

Norway has been a dominating influence on the development of action research in Scandinavia, where the ideas of Kurt Lewin were used to underpin what came to be known as the Industrial Democracy Project. In the 1950s and 1960s, socio-technical experiments in industrial development were taken up across Denmark, Sweden and Finland, supported in some cases by government funding. Intimately tied up with consensus within the workplace, these experiments foundered as neo-liberal ideas took hold to a greater or lesser extent within the respective countries. Criticism of action research in the 1970s came from a number of directions, and that criticism has led to a different emphasis in each of the Scandinavian countries. For some, the approach had become appropriated by capital and the state as a mechanism for imposing the neo-liberal agenda. Conversely, government and industry were concerned that the promise of action research had not been realized, particularly in the area of innovation. Many of the experiments had failed to move beyond short-term change in individual factories and workplaces. For those working in the social fields, action research was seen as having failed in its task of achieving social change. The strongest critique, however, came from university-based social scientists in Denmark and Sweden who argued that action research was not proper research but rather a form of consultancy. This view still prevails in Denmark and to a lesser extent in Finland and Sweden despite the call in the latter countries for universities to engage in co-operating with society on issues of social change. By contrast, in Norway, action research has become mainstreamed and embedded in the governmental system, largely due to the efforts of Bjørn Gustavsen and Morten Levin, leading academics in that country who also have a strong international presence in action research. In Denmark, the University of Roskilde has been prominent in maintaining action research.

In Sweden, action research was promoted largely outside the university system, particularly through the activities of the National Institute for Working Life, which grew to include several research establishments in Stockholm, Umeå, Östersund, Norrköping, Göteborg, Malmö and Visby, with a staff of roughly 400 researchers, auxiliary staff and management/administration and an annual state budget of €40 million, as well as research grants of about €6 million to €8 million from diverse funding agencies. In 2007, the newly elected government closed the institute. The action research torch was also taken up by the Association of Local Authorities. Many local authorities have set up research and development units to compensate for

the lack of applied research in universities. Building on the tradition of the study circle, these research units developed programmes of research and development to support education, health care and other activities of the local authorities, using action research methodology to support learning and practice development. Individuals working in these research units often had links with local universities. The use of the term *Interactive Research* allowed action research as currently practiced to distance itself from the failures of the 1960s and 1970s and to reposition itself within the academic discourse. There is now a Swedish Interactive Research Association hosted by Jonkoping University College.

Interactive Research as Learning and Dialogue for Change

The focus on interaction terminology highlights the importance placed in this type of research on the role of dialogue and interactive learning through participation in the research process. A variety of techniques have been used to encourage this communicative praxis. Three forms have become popular: the Dialogue Conference, the Search Conference and the Future-Creating Workshops. The Dialogue Conference, originally systematized by Gustavsen and John Shotter, is a structured process of dialogue which encourages reflection and learning. It is the most popular form of democratic dialogue used in Interactive Research. The Search Conference, which is more recognized outside Sweden, is not dissimilar but focuses on future planning and tends to stress systems thinking and the emergence of ideas from interaction. Future creating is a form of interactive dialogue, which has adopted a critical theory approach to action research by encouraging participants to explore a utopian vision and then to compare it against reality. Notwithstanding the popularity of these three forms of dialogue, the key emphasis in Interactive Research is that the participants are directly involved in the analytical process and the role of the researcher is one of providing and creating a supportive joint learning process where there is enough time to develop a reflexive trust between the participants, rather than unreflective confidence.

INTERNATIONAL COUNCIL FOR ADULT EDUCATION

The International Council for Adult Education (ICAE) played a key role in the development of participatory research in adult education. The ICAE was founded in 1973, following the third UNESCO World Conference on Adult Education in Tokyo in 1972, to give a voice to practitioners and academics. A range of initiatives had developed in the early 1970s in adult education and social movements in different parts of the world to develop alternatives to classical social science research, in order to involve the active participation of the people, overwhelmingly in marginalized social groups, whose experiences were the subject of study in identifying their needs and determining how learning might help fulfil them. Common themes in these initiatives, which included a variety of community-based approaches to the creation of knowledge, were first identified as 'participatory research' in Tanzania. ICAE recognized the value of these approaches and developed a global network of participatory research to promote strategies for engaging people in articulating the learning needed to help transform their lives.

A key role in the development of participatory research was played by ICAE's first research officer, Budd Hall. Whilst working in Tanzania, Hall, like many others, became dissatisfied with the way the supposedly neutral disciplines of mainstream social science served to reinforce the dominant social order rather than to empower communities without access to power and agency. He acted as a catalyst in bringing together Julius Nyerere's holistic ideas on education for development, the pedagogy of Paulo Freire and in particular his approach to 'thematic investigations' and Maria Liisa Swantz's experience in participant engagement in women's development in coastal Tanzania to identify alternative approaches grounded in the active engagement of the communities affected. This work was paralleled in Colombia, where Orlando Fals Borda had developed Participatory Action Research; in the engagement of landless rural farm workers in agrarian reform in Chile and in community

engagement strategies in communities driven by sectarianism in Northern Ireland.

On his appointment as ICAE's first research officer, Hall brought a number of these initiatives together in a themed issue of ICAE's journal *Convergence*, which had an immediate impact. An invitation in the journal for engaged readers to exchange experience produced a flood of responses and led ICAE to develop a Participatory Research Project, which rapidly developed into the International Participatory Research Network. During the late 1970s, ICAE hosted the expanding network and played a vital role in linking academics and practitioners. By 1978, there were nodes of the network in Canada, India, Tanzania, Venezuela and the Netherlands.

The networks identified four principal objections to traditional social science survey methodologies, as summarized by Rajesh Tandon in 2005. First, a focus on knowledge generation as the key purpose of social science research, in a world where there is a wide gap between available knowledge and its utilization, leads to research that fails to be used to improve social, economic and political systems. Second, the supposed neutrality of the scientific research method reinforces existing power paradigms, as the pursuit of rigour leaves the academic researcher firmly in control of the process, thereby reinforcing the marginality of the people studied. Third, traditional methods rely excessively on thinking, observing and conceptualizing and, as a result, oversimplify the complexity of communities' lived reality and sit uncomfortably with adult education's concern for engagement in pursuit of justice and equality. Lastly, institutionalized knowledge centres (universities, institutes and colleges) delegitimize traditional forms of knowledge.

By contrast, Hall suggests that participatory research principles include the following: (a) research methods have, inevitably, ideological implications; (b) the research process needs to directly benefit the communities involved and (c) the communities affected need to be involved from the shaping of the problem to be addressed to agreement on the methods to study the problem and identify solutions, to the interpretation of findings. The research process is characteristically dialogic and aims to have a lasting impact on the skills and engagement of the community. Above all, it is research focused on effecting change to secure the rights of marginalized communities, especially their right to be heard in an enlarged democratic discourse.

In 1978, in a further clarification of the process, the international network argued that the political impetus for participatory research originates in the community or workplace itself. The work needs to be grounded in the lived reality of the affected communities in all their complexity. To that end, there must be an emphasis on

qualitative inquiry, to offset the limitations of survey data. Interpretation needs to be a collective process involving all the actors, and it needs to be complemented by active networking within the marginalized communities.

Over time, the network became a self-reliant group of activist researchers, maintaining a close relationship with the ICAE Secretariat. Whilst continuing to foster new initiatives, ICAE's own contribution to the development of participatory research then shifted to its regional associations and its thematic networks. Perhaps most notable among these has been the Society for Participatory Research in Asia, co-ordinated by Rajesh Tandon in India, which has maintained an active influence on the Asia South Pacific Bureau for Adult Education, ICAE's regional association.

ICAE has also fostered action research activity through its International Academy for Lifelong Learning Advocacy, which embeds participatory research skills in the practice of adult educators and social movement activists, and in co-ordinating national and local monitoring of the extent to which governments honoured the international agreements affecting the right to education that they had entered into through the UN process. Its members have also fostered the growth of the adult learners' movement, which contributed powerfully to the most recent UNESCO World Conference for Adult Education (CONFINTEA VI) in Brazil in 2009.

INTERNATIONAL PARTICIPATORY RESEARCH NETWORK

The International Participatory Research Network (IPRN) was responsible for the creation and dissemination of the early theories and practices of the concept of participatory research. *Participatory research* is a term that was first articulated in Tanzania in the early 1970s

to describe a variety of community-based approaches to the creation of knowledge by community-based researchers influenced by the philosophy of Julius Nyerere, the practices of Marja Liisa Swantz (1975) and the political epistemologies of Paulo Freire (1971). Participatory research combines the three activities of social investigation, education and action in an inter-related process.

The IPRN, associated with the International Council for Adult Education, was begun in 1976. Budd Hall was the founding co-ordinator of the IPRN from 1977 to 1980. From 1980 to 1992, Rajesh Tandon of the Society for Participatory Research in Asia led the network and helped extend and deepen the ideas. The IPRN was an active global network in the early 1990s, when the decision was made that the concepts and values were widely known and did not need the kind of promotion required in the early days.

Founding of the Network

The idea for a network arose from the response to the publication of the special issue of *Convergence* on the subject (1975). The adult education community and related community development activists bought out all the copies of the journal. It was clear that many people in the majority world and people working with or for marginalized persons in the rich countries were actively engaged in research projects which were very different from the standards of the day in most of the universities of the world.

The next impetus came from the First World Assembly of the International Council for Adult Education in Dar es Salaam, Tanzania, in 1976. A recommendation was made to the world adult education community that adult educators should be given the opportunity to learn about and share their experiences in participatory research. Edward Jackson, an activist adult educator from Canada, was a participant at the Dar es Salaam conference, and he, dian marino and Deborah Barndt helped found the Toronto group, which ultimately gave birth to the IPRN.

The 1977 international conference on Participatory Action Research organized by Orlando Fals Borda, a Colombian sociologist, and a group of Latin American and other activist-intellectuals was further inspiration. Participatory research arose in part from a re-examination of the role of intellectuals in the struggle for social justice. There were debates between those who felt that it was the role of intellectuals to lead the social and political movements on behalf of the people and those who said that it was time to build the democratic struggle from the ideas of the poor and excluded themselves. Participatory research emerged as a process of politically engaged co-construction of knowledge.

Upon Hall's return from the Cartagena conference and a visit to Francisco Vio Grossi, a Chilean sociologist in exile in Venezuela, in 1977, the Toronto Participatory Research Group organized an event where the decision to start the IPRN was made. Among the most important political principles of the network was the insistence that each node or networking group working in the various parts of the world would be autonomous and self-directing. They would each be committed to building an international network, but the Toronto group would not be in charge. The initial principles were the following:

1. Participatory research involves a whole range of powerless groups of people—the exploited, the poor, the oppressed and the marginal.
2. It involves the full and active participation of the community in the entire research process.
3. The subject of the research originates in the community itself, and the problem is defined, analyzed and solved by the community.
4. The ultimate goal is the radical transformation of social reality and the improvement of the lives of the people themselves. The beneficiaries of the research are the members of the community.
5. The process of participatory research can create a greater awareness in the people of their own resources and mobilize them for self-reliant development.
6. It is a more scientific method or research in that the participation of the community in the research process facilitates a more accurate and authentic analysis of social reality.
7. The researcher is a committed participant and learner in the process of research—in other words, a militant rather than a detached observer.

In 1978, Francisco Vio Grossi hosted a meeting of the IPRN at Simon Rodrigues University in Venezuela. Rajesh Tandon joined the group, and five nodes in the network were created: North America, Asia (Rajesh Tandon), Africa (Yusuf Kassam), Europe (Jan de Vries) and Latin America (Francisco Vio Grossi). The IPRN organized a series of meetings around the world and published many reports and books to increase awareness of ideas, deepen understanding of the work, build support for others who were trying such work and show people in various locations that these ideas had world resonance and relevance. The IPRN consistently honoured the fact that the majority world had been the intellectual source for these exciting new ways of working and continued to inspire us. While the IPRN is

no longer a formal network, the ideas and values behind it can be seen in the emergence of the Global Alliance on Community-Engaged Research in 2008.

INTER-ORGANIZATIONAL ACTION RESEARCH

Inter-organizational action research (IOAR) is a particular articulation of action research which identifies distinctive features and experiences, whereas action research focuses on the shared issues and relationships across two or more organizations. This entry provides an outline of IOAR's origins, traditions and key ideas. Examples of applications are illustrated before considering the particular distinctiveness of IOAR in relation to action research.

Origins, Traditions and Key Ideas

Ideas for IOAR are particularly associated with Rupert Chisholm in his work on developing networks. IOAR has a number of distinguishing features, including its emphasis on engaging multiple participants from many diverse organizations in complex systems of change.

Key ideas in IOAR are inter-organizing insight, insider-outsider, inter-organizational partnerships or networks, boundary spanner and institutional entrepreneur.

Traditional Action Research

Action research works on the epistemological assumption that the purpose of academic research is not just

to describe, understand and explore but to change something. Therefore, there is an opportunity that through action research, an inter-organizational group may question and improve their own thinking and acting about how they work together, be it networking, co-operation or collaboration. The origins of action research lie with system change and improvement simultaneously with generating knowledge about that system, as traced to Kurt Lewin's concern with minority social issues and to developing world applications of Participatory Action Research for social change. These traditions implicitly engage action research across organizational boundaries, as does the tradition of whole industry sector change action research associated with Norway. However, in recent years, greater attention has been accorded to action research within a single organization (intra-organizational action research) and first person action research, focused on the individual's practice development. IOAR has distinctive challenges deriving from the complexity and multiplicity of the actors and groups involved.

Core Components of the Action Research Cycle

IOAR follows the typical action research cycle of pre-step, preparing study, planning, taking action, questioning, reflecting, searching and capturing learning. As with any action research, important elements are who initiates the action research for the cycle to commence and how people are drawn into the processes of inquiry and action. Somebody, somewhere within the inter-organizational system needs to trigger action in the form of a pre-step, meaning that a problem needs to be raised; there needs to be a challenge of taken-for-granted ways of doing things. This catalyst could be a member of one of the organizations, perhaps the lead organization or indeed a person working with the inter-organization arrangement. The initiator, whether individual, group or organization, is described as reflecting qualities of institutional entrepreneurship, in the sense of expressing a vision of divergent change and acting to leverage resources, mobilize allies, develop alliances, create co-operation and bridge political stakeholders across organizational boundaries to push for particular arrangements with regard to a policy interpretation.

Distinguishing Features of Inter-Organizational Action Research

IOAR has been categorized by Chisholm along five dimensions:

1. Level of system change
2. Organization of the research setting

3. Openness of the action research process
4. Intended outcomes
5. Role of the researcher

Level of System Change

The level of system change may vary. It could entail a specific multi-agency team, drawn, for instance, from health, education and criminal justice bodies, collaborating to improve their effectiveness as a children’s services committee in maximizing life chances for children in their locality. Other examples include development and implementation of a community strategy for a region, through the participation of community representatives and members of multiple public and voluntary sector organizations. At the other end of the scale, the level of system change could be the whole society.

Organization of the Research Setting

When members from distinct organizations come together collaboratively, the ways in which they interrelate, self-regulate and communicate becomes the pattern of organizing. A key contextual factor is the nature of the pre-existing collaborative working arrangement. This can be categorized across the continuum (as shown in Table 1), which increases in integration and formality from left to right.

Collaborative organizing typically combines loose-tight coupling. To a large extent, the arrangement is loosely self-organizing, with all members recognizing each other as equal peers, sharing power and responsibility for designing and directing their shared activity. This coincides with an element of tighter organization, for example, through a steering group or project board and a series of organized whole-system and subgroup events that provide an infrastructure for inquiring conversations, collective reflection and generation of systemic information. For example, stakeholder

conferences might engage and consult with hundreds of participants through formats such as café society, facilitated workshops and exhibitions.

To embark on a journey of action research, the inter-organizational arrangement requires the following:

- There should be a collective understanding of the problem or issue to be resolved.
- *The art of boundary spanning*: Individual behaviours mobilize relationships and facilitate networking, empathy and interdependence.
- *Collaborative leadership*: This entails bringing persons together and breaking down barriers to enable cross-boundary work to happen. In this sense, collaborative leadership provides a supporting architecture, whereby a process of new learning occurs and new ways of behaving emerge, so that the whole group can self-govern and all members can participate in joint decision-making, including the decision to partake in an action research process.

Openness of Action Research Process

As with traditional action research, IOAR also traverses a spectrum of openness from the contribution by all members to an initial decision to engage in action research for change and data collection through to full participation at all stages, characteristic of Co-Operative Inquiry or Participatory Action Research.

However, if the intention of IOAR is to develop more effective patterns of organizing, an inter-organizational arrangement needs to take full ownership of each stage of the action research cycle, from identification of the issues to planning action from analysis of the context and the problem, to taking action and reviewing the outcomes of action, both intended and unintended.

Openness in the action research process requires participants to be open to working together, open to reflecting together and open to learning and change.

	<i>Networking</i>	<i>Co-Ordinating</i>	<i>Co-Operating</i>	<i>Collaborating</i>
Prime purpose	Information exchange	Greater integration in services delivery/ production	Exchanging knowledge, people + resources for common purpose	Mutual enhancement + transformation for achievement of common purpose
Resource sharing	None	Minimal	Moderate	Full sharing of risks and rewards
Motive	Economic	Economic	+Learning	+Change

Table 1 *Typology of Inter-Organizational Collaborative Arrangement*

SOURCE: Adapted from Himmelman, A. T. (1996). On the theory and practice of transformational collaboration: From social service to social justice. In C. Huxham (Ed.), *Creating collaborative advantage* (chap. 2, pp. 19–43). London, England: Sage.

Participants need to engage with an orientation that is open to the potential recognition of 'We need to change and I need to do X'.

Intended Outcomes

A shared purpose and some commonly understood goals by members is fundamental, as a framework within which participants engage in cycles of inquiry, action, reflection and further planning. This might be framed, for example, as a central action research question: What needs to occur to improve inter-organizational collaboration at our local level? Or it might focus on specific problems: How do we improve our rate of new product development?

A useful categorization of the purpose for engaging in IOAR is Paul Coughlan and David Coghlan's distinction between primarily strategic, learning and transformational networks. Strategic networks have economic goals, such as to reduce costs or increase market share. Learning networks have the intention of using experience and exchange to increase capability and knowledge. Transformational networks, such as the full 'collaborating' arrangement in Table 1, expect iterative changes both within the relationships and processes of inter-organizational working as well as within each individual member organization.

Role of Researcher

IOAR raises the questions as to who is or are the researchers. Do they also take action? Are they external experts, or are they co-researchers? In practice, IOAR researchers may be insiders working within one or several member organizations, or they may comprise outsiders invited into the world of the inter-organizational system.

Their research role is to design processes for generating information and to frame analysis and sense making. Their action role is to create ways for surfacing learning about the system, to frame questions and to create opportunities for network members to learn. The more complex and multi-agency the collaboration, the more the role of action researchers is likely to encompass boundary spanning, in the sense of identifying and surfacing problems, facilitating relationship building and mobilizing action and learning across professional and organizational boundaries. An external co-ordinator with organization development skills has often been used to help cultivate such relationship building.

Key to achieving systemic change through IOAR is the emphasis on collective reflection and the role of inter-organizing insights. This may mean enacting new ways of network organizing, learning from recognizing, discussing and potentially transforming

the social power relations central to organizing. In this sense, the research and action can be both about aspects of the collaboration's work activity and about the wider organizational or systemic life of which its members are a part. IOAR can be employed for organization or systemic change by connecting subgroups in dialogue with each other. Not only can this lead them to identify what might need to change, but the action research collectivity can also be a place for action, in that it is itself a social community in which people can examine the politics that surround and inform the choices and decisions which constitute organizing and begin to organize differently.

Distinctive Challenges of Inter-Organizational Action Research

Compared with first person action research or insider organization action research, IOAR has distinctive challenges arising from the requirement for engagement and co-ordination of multiple actions by multiple actors, connecting to multiple groups and organizations.

Barriers to effective collaboration include personal agendas, individual politicking, power inequity amongst participants, low trust, contradictory goals, poor managerial relationships, geographical distances, cultural differences and *collaborative thuggery*, Chris Huxham and Siv Vangen's term to categorize leadership that does not empower, involve or mobilize but manipulates the collaborative agenda.

Management or leadership within and across inter-organizational working requires distinctive capabilities in order to handle the paradoxical demands for both unity and diversity.

Organization Embeddedness

The inquiry basis of action research can be quite threatening in an inter-organizational context, particularly when the organization cultural norms of members do not encourage activities such as questioning taken-for-granted rules and norms, fostering courage and inciting action. Boundary spanning requires that those involved can divest themselves of their organizational embeddedness, prioritizing their own individual or agency objectives without the spirit of openness and social bonding required for collaborative practice.

Insider-Outsidership of Researcher(s)

Action researchers in IOAR are put in a distinctive position of being simultaneously insider and outsider. They may be insiders in the sense of belonging to one of the network organizations but outsiders in relation to other member organizations. Or they may

be 'insiders' of the inter-organizational collaboration, in the sense of allying themselves with the network objectives, whilst being outsiders in relation to each individual organization. As such, they need a distinct set of capabilities that includes political skills to manage their superiors, the ability to boundary span and a capacity to simultaneously hold demands for both unity and diversity.

INTERPRETIVE COMMUNITY

See Listening Guide

INTERSUBJECTIVITY

Intersubjectivity emerges through the active engagement of individuals who mutually construct actions, interactions and meanings together. This active engagement may be the result of the conscious and unconscious responses of individuals to each other. Intersubjectivity is defined as the sum of interactions mediated by and through the larger external environment that results in the production of shared meaning, norms and values, which, in turn, lead to social, cultural, political and economic structures. The extent to which a group of individuals establishes an effective basis for intersubjective agreement is an important focus for action researchers. The implications for understanding how and to what extent intersubjectivity effectively leads to

group identity, shared meanings and collective action is a critical feature of successful action research.

Intersubjectivity is a transdisciplinary concept with roots in the phenomenological philosophy of Edward Husserl. The term may be found in literature spanning all the major social sciences and generally is used to describe the experiential nature of socially constructed phenomena. Social scientists have increasingly relied on the concept of intersubjectivity to draw analytical insights from empirical observation. Social science studies of collective behaviour routinely note that the division of labour within groups can lead to disagreement about the nature of a problem, the parameters of a decision to be made and so on.

Those who draw on the concept of intersubjectivity to describe social phenomena understand that the sense of 'self' cannot be extracted from the rule-bound contexts that shape human interaction. G. H. Mead referred to the symbiotic relationship existing between the self and the 'generalized other'. Intersubjectivity is constructed from the complex integration of the selves of a finite number of individuals, their generalized others and the symbiosis of them. As a construct of human consciousness, intersubjectivity is fuelled through the perceptions of individuals. Individual human perception is framed through a dialectical exchange between the individual and the wider environment.

Intersubjectivity as a feature of human perception and collective social reproduction has been featured within the philosophy of science literature in relation to objectivism and subjectivism. Those adhering to an objectivist (often referred to as positivist) orientation tend to view reality as existing independently of any individual observer and describable through the ascription of natural laws and testable hypothesis. A central assumption of objectivism is that the observer can be extracted from that which is being observed. Applied to Mead's theory of the self, objectivists approach the generalized other as something that persists independently from the self.

Those scholars adhering to a purely subjectivist lens give primacy to the perceptions of the individual. Taken to its most extreme, reality is nothing but individual perception. Continuities found within social institutions and other social structures are mere 'accidents'. In a purely subjectivist approach, perceptions mediated through the self are, in actuality, all that exist. The generalized other appears as a figment of the imagination.

To avoid falling into the trap of absolute relativism, those adopting an interpretivist social science orientation have gravitated towards the socially constructed features of intersubjectivity, to the extent to which much of mainstream sociology, anthropology and social psychology have adopted its central premise: that social reality is predicated on social interactions

between individuals and between groups of individuals and their wider external environments.

Communicative Rationality and Collective Practice

According to Husserl, and later reinforced by Jürgen Habermas, intersubjectivity emerges from decidedly rational processes. Husserl's view of rationality has been critiqued for being too simplistic, in part because he (and many of his Enlightenment predecessors) failed to draw distinctions between different forms of rationality. Some forms of rationality are predicated on objectivist preconditions. Habermas refers to this as 'instrumental rationality'. However, the varying capacities of individuals to construct and reconstruct a rationale for their actions may be labelled as being 'rational', 'non-rational' or 'irrational', depending on who is doing the labelling. Habermas is attracted to the concept of intersubjectivity (and the wider phenomenology project that anchors it) because of its explanatory power for describing the mediation of social reality (what he deems the 'lifeworld') through the lens of social interaction. Intersubjectivity becomes a necessary precondition of 'communicative rationality'. According to Habermas, the establishment of a communicative rationality between social actors is needed to ground mutual agreements about collective action.

Although intersubjectivity can be used in the social psychological sense as a means to abstractly describe how individual identity is formed through collective action, action researchers are more likely to be focused on understanding how professional, community or civic identity is formed through collective practice and how, in turn, practice is informed by and through individual identity. In this context, intersubjectivity can be used by action researchers to bridge the individual with the collective in substantive ways.

It has been noted earlier how intersubjectivity is formed through conscious and unconscious responses. As Alfred Schutz has suggested, intersubjectivity is more often than not mediated through taken-for-granted assumptions that individuals possess about themselves, other selves and the generalized others who populate their lifeworlds. Effective action research can aid individuals and groups in translating tacit, taken-for-granted knowledge into explicit knowledge. In other words, action research can lead to the development of conscious responses of individuals to their intersubjective lifeworlds. Action research processes can facilitate intersubjective negotiation predicated on communicative rationality. Action researchers can help surface the norms of communicative rationality that exist within a group or provide a consultative role in helping to

establish new communicative norms. How this is done is the subject of the next section.

Intersubjectivity in Action Research

Action researchers are, by definition, active participants in the lifeworlds of the subjects and objects being studied. Action research cannot be undertaken exclusively through an objectivist orientation. Action researchers cannot, by definition, distance themselves from their objects of study. In other words, action researchers enter into the intersubjective realities of those who are participating in the study. In some instances, action researchers, themselves, may be active practitioners with histories of prior engagement with those other people, events and objects implicated in action research projects.

When structured well, both action research processes and results will inform the negotiated meaning that unfolds between individuals. Action research designs can play a role in bringing tacit knowledge into consciousness. Chris Argyris and Donald Schön's classic use of action research to inform organizational learning provides an excellent example of this process. In their work, action research facilitates the double-loop learning of participants. Double-loop learning occurs when the underlying governing rules, norms and shared meanings are brought to the surface, critically examined and modified if and when needed. Double-loop learning is fostered when the intersubjectivity of a group is brought to consciousness.

There are any number of techniques and methods that action researchers can use to bring intersubjectivity to consciousness. Virtually, all forms of qualitative methods that follow the interpretivist tradition are capable of doing this. Action researchers who draw on informants' narratives are pressed to represent what they believe to be the intersubjective realities of a group. A standard technique to draw out this intersubjectivity is the triangulation of individual perceptions. For example, individuals are asked about their perceptions of an event or activity. The perceptions of each individual are recorded. The action researcher then constructs an intersubjective picture of the project by triangulating the perceptions of the stakeholders who were interviewed. A nuanced, multifaceted picture of the event or activity is presented. Action researchers close the loop by feeding this multifaceted representation of the event or activity back to the group of stakeholders. In doing so, the action researcher presents a picture of the group's intersubjective interpretation of the event or activity.

The result of this kind of action research process becomes, unto itself, a generalized other that the group must encounter and respond to. This process may end up reifying what stakeholders report to be already

known, or it may draw out new insights or ways of perceiving that can have a profound effect on the future direction or course of a group's collective actions.

Other social research methods may be employed to bring intersubjectivity to the surface of the collective consciousness. Surveys and polls are often used to bring clarity to the collective will or intersubjective perceptions of large groups. Bayesian statistics and Boolean networks can be used to render probability distributions of aggregations of individuals' perceptions. Within an action research context, statistical models of this sort are used by stakeholders to inform future individual and collective actions. More recently, computer models have been devised to simulate group intersubjectivity using system dynamics and agent-based modelling approaches. When these models are undertaken using participatory or mediate modelling approaches, groups may carry out collective scenario planning and may use the act of jointly constructing models and engaging with models to better understand the relationship between individual perception and identity, and collective action.

In sum, the concept of intersubjectivity is a critical feature within almost any successful action research project. A diversity of research and modelling approaches may be employed to reconstruct the intersubjective frameworks that guide virtually all social groups—ranging from small teams, committees and task forces to large institutions such as bureaucracies. By tapping into the social science and philosophical literatures that have drawn on intersubjectivity as a central construct, action researchers may ground their empirical observations and partnerships with stakeholders in theories of phenomenology: of the self and the generalized other. In this manner, they may better position themselves as agents within an intersubjectively constructed reality and use action research approaches to foster learning, more effective practice and desirable outcomes.

INTERVENTION RESEARCH IN MANAGEMENT

Intervention Research in management (IRM) shares a field-oriented methodology and an experimental logic with action research, but it differs from it by its basic assumptions about the essence and history of management research. IRM supposes the close combination of (a) the theoretical perspective that management situations with the most important research potential are the ones that allow major revisions of established management theories-in-use and (b) a research protocol that implies close collaboration between a pioneering organization and a skilled academic intervening research team. This entry describes the theoretical foundations of IRM.

IRM and the Foundations of Management: Building on Follett's and Barnard's Legacy

IRM combines a theoretical perspective and an intervention protocol in order to revise existing management theories-in-use and co-invent new models of collective action, in a management research and development (R&D) logic. Hence, the epistemology of IRM has deep common roots with the foundations of management as defined by Mary Parker Follett and Chester Barnard, who both introduced general grammars of action and postulated a science of management that would result from immersive interactions between the observer and the observed. Barnard formalized the general principles of a new epistemology, a science of management that would consider organization as a subjective process which can only be known organically and formalized accurately (i.e. consistent with experience) by the individual. Therefore, an organic applied social science, in contrast to the professional science abstracted from the interactions and interdependencies of living and acting, would have unprecedented explanatory power. Rejecting an epistemology

that separates theory from practice, Follett and Barnard pursued an integrative science that exploited the creative possibilities of conscious organization, beginning with organizing oneself. For them, it was a scientific, creative and ethical relation at one and the same time. It meant theorizing formal organizations as an experimental condition and method. This way of conceiving the dynamics of collective action is very close to IRM principles and logic: IRM could well be the research programme consistent with Follett's and Barnard's legacy.

Essence of Management Research: Models of Collective Action

IRM assumes that there is no universal protocol to study action but research can study models of collective action through which action is made visible. Therefore, its programme is to understand how models of action are discovered or invented, how they are tested, discussed or validated. For instance, accounting, which is a model of action, makes business observable and simultaneously shapes and orients it. Management models are both a subset of all models of action (all action is not managerial action) and exemplars of models of action. The business world has long been a relevant place to study the invention of models of action. Companies are social entities that regularly have to redesign themselves in order to survive: They are under a permanent change-oriented process through self-intervention. More generally, organizations are also places where innovative models of action may emerge.

If management research is the discovery and study of models of action, it is not the privilege of the academy only. Major management innovations were made by managers or through collaborations between managers and academics. For example, Kurt Lewin and Alfred Marrow at Harwood conducted an 8-year collaboration that contributed to the establishment of action research and new theories and applications of change management. Therefore, the role of management research is not limited to non-participatory observation of what managers do. The essence of management research is understanding, inventing and criticizing models of collective action. Inventing means being a pioneer in designing alternatives to existing management theories-in-use.

IRM: An R&D in Management Approach

IRM emerged progressively from numerous collaborative research programmes with companies and state agencies at Paris School of Mines. Its issues are problems that suggest management breakthroughs. It aims

at improving models of action, not action, and the intervention of IRM researchers on the field can be understood as collaborative R&D in management. Like any field research, IRM has to follow specific methodological precautions. The practice of IRM requires five basic preconditions:

1. A partner with a pioneering logic
2. An open management issue
3. An assessed research potential
4. A contractual commitment to a research issue
5. A laboratory with a legitimate research potential in management

Two main principles monitor IRM:

1. *The principle of free academic investigation:* The first principle means a combination of free interviewing (the researchers have full access to the organizational perimeter), warranted isonomy (a priori equal attention to each actor on the field), confidentiality of all individual interviews (a basic rule, to ensure freedom of expression), a capacity to create new empirical material (beyond the interviews: enhanced exploratory power, thanks to the IRM collaborative protocol), the principle of controlled design (the emergence of new management models is a design process that requires some form of invention) and management innovations evaluated as rational myths (the role of the research team is to help clearly distinguish between the two components of management innovations: a rational response to a management problem and a mobilizing myth that creates trust, energy and commitment).

2. *The principle of joint and continuous monitoring:* The research team and the partnering organization together define, implement and steer the IRM process. Together, they generate the main outputs, theoretical and practical: local contributions to management breakthroughs, publishable case studies, revision or invention of management models.

Table 1 summarizes the preconditions, monitoring principles and main outputs of IRM.

Research Potential of Management Situations: Established and Contextual Theories-In-Use

IRM aims at improving models of action. Yet revising a model of action becomes interesting for research only if some well-established assumptions are rigorously revised. But how can researchers establish the research potential of an empirical management situation? The notion of theory-in-use (versus espoused theory) can

Management Situation		Existence of a CTU		
		Yes		No
Existence of an ETU	Yes	ETUs and CTUs are identical and <ul style="list-style-type: none"> • efficient: <i>very limited research potential</i> (illustrative case study) • not efficient: a <i>potential revision of existing ETUs</i> (cf. 'No-no' case) 	ETUs and CTUs are different: <i>moderate research potential</i> : explain the discrepancy, and revise either CTU (if not efficient) or ETU (if efficient CTU)	Existing ETU would be efficient, but actors do not know about it (lack of expertise, lack of organizational maturation): <i>moderate research potential</i> (contribution to the validation of an existing ETU in a given context). Or higher research potential if the empirical situation proves to be a counter-example for the ETU (ETU proves to be inefficient): <i>potential revision of existing ETUs</i>
	No	Existing or revised CTU as a new model? (labeling 'as is' or improving + labeling): <i>high research potential</i> (make the theory that gives to the model its general value as a model of collective action) <i>Limited research potential</i> if CTU proves to be already referenced or finally close to existing ETUs <i>Chandler, labeling the 'M-form' from Du Pont and GM's invention of multi-divisional structures</i>		Open exploration for a new model (invention/labeling): <i>maximum research potential</i> (invent a new management model and make the theory that gives to the model its general value as a model of collective action) <i>Limited research potential</i> if CTU appears easy to invent from existing ETUs or through a combination of CTUs in similar, well-documented situations <i>Ohno, inventing and labeling the 'just-in-time' organization of production</i>

Table 1 A Typology of Research Potential Defined by Joint Analysis of Existing CTUs and ETUs

NOTE: CTU = contextual theory-in-use; ETU = established theory-in-use.

be extended to note that a management theory-in-use can be either established or contextual. A contextual management theory-in-use (CTU) is a set of management assumptions, rules and schemes that are common to members of an organization. An established theory-in-use (ETU) describes the same kind of material as CTUs when this material is actually legitimized and validated outside the organization by a widely referenced set of academic and professional supports. For instance, a variety of quality insurance techniques and behaviours exist in organizations (CTU), and ISO 9000 norms are the corresponding ETU; many managers take balanced decisions relying on multi-criteria evaluations (CTUs) and multi-criteria decision-aiding methods.

With such categories in mind, researchers may face four different empirical situations (Table 2): (1) actors know how to deal with the situation (they have a CTU), and there is also an ETU for that situation; (2) an ETU exists, but actors in the organization do not know about it and have no CTU; (3) actors have a CTU, but no ETU is referenced in the academic literature or professional established practices and (4) actors do not know

how to cope with the situation (no CTU), and no ETU is referenced.

Clearly, the more open the situation with respect to the revision of existing ETUs, the higher is its research potential. Local tensions between ETUs and CTUs are also major signals of research potential for IRM. The knowledge with the highest value is not everyday knowledge produced to solve routine problems. It is the knowledge produced when a pioneering company invents, consciously or not, a new management model. At this moment, the same set of new knowledge used by managers to radically transform the situation can be interpreted by researchers as a potential scientific discovery.

By way of an introduction, it is important to note that in action research, interviews often become a kind of dance or informal conversation between an interviewer and an interviewee. The idea of a dance suggests the highly reflective way in which participants discuss, share information and co-create a narrative about a particular experience, event or set of issues. Unlike traditional research, the roles between the two participants may blur and shift, and the creation of a narrative is always local and specific to those involved. It is meant to legitimate the experiential knowledge of the person/people being interviewed as well as enhance the skills of the interviewer/listener. It may shock, sadden, galvanize or bore, but it will always generate data or information about the question in focus.

INTERVIEWS

Interviewing is the most common way of collecting data in action research and is used in both quantitative survey research and qualitative inquiry. If action research involves observation, analysis and then doing, interviews are central to the first two steps. This short overview focuses on qualitative interviews in particular, outlining their history, their various forms and configurations and their preparation, process and analysis.

Types of Interviews

Interviews have been used in the social sciences since the nineteenth century, with the closed-ended question survey proving to be the most popular until the 1970s. After that, less structured and more open forms of interviews started capturing the attention of researchers less concerned with emulating the scientific method and more interested in the lived experience of people as told by those people. With the advent of action research and its goal of local, social, political, organizational or

community change, open-ended and more creative collection methods became even more important.

Indeed, at this point, just as there are many ways to collect data, in action research, there are many kinds of interviews. These include individual structured, semi-structured and narrative approaches as well as group interviews or focus groups. In addition, interviews may be formally or casually conducted, face-to-face, over the telephone or online. The interview data may be captured through field notes, flip charts, audio tapes or using video cameras, to name just a few methods. The team's choice of which type of interview to do will depend on the community of interest and their cultural, political and ideological approaches; the theoretical orientation of the project; the research questions; ethics; the length of time they have to do the work; their access to equipment for recording and transcribing data; how many people need to be interviewed and compensated and, of course, resources for all of the above.

Roles and Relationships

As with other types of action research and ways of collecting data (e.g. questionnaires, observation or visual methods such as Photovoice), the interview experience will hinge on how much work has gone into establishing roles and relationships beforehand. For instance, those doing the interviews should ideally be people who have stepped forward from the community of interest doing the action research; who have been helped to prepare for, practice and carry out 'test' interviews and who genuinely want to do this kind of data collection. Ideally, they will have been involved in the research project from the beginning, deciding on the research questions, thinking through the ethics of the work and planning how best to collect the kind of data needed to 'act' in the ways and means the group needs most. It is important that the interviewers on the team are comfortable with their role, have co-created the questions on the interview guide and have the support they need both before and after the interview takes place. This could include one-to-one or group debriefings where interviewers can discuss and support each other, sharing tips and insights on the process.

Then, there is the relationship with the person being interviewed, which, however brief, is also central to the process. The worst thing an interviewer can do is rush in, turn on a tape recorder and start asking questions. Instead, the action research team will have already discussed and planned for the safety and comfort of both interviewee and interviewer. During the recruitment stage of the work, they will have asked people where

they would feel most comfortable being interviewed, by whom (i.e. a self-identified woman perhaps), at what time and what they need ahead of time (i.e. a copy of the interview guide, a contact number and, if necessary, a consent form). The team will have allocated resources for transportation to and from the interview site, for refreshments and/or meals and for recognition of the time, effort and knowledge shared. The interviewer will know that time spent at the start just chatting, drinking coffee, going through the consent form and explaining the research project is invaluable. For instance, in some forms of Afrocentric interviewing, the interviewer may bring a variety of foods to the interview and may experience an extended 'greeting' of an hour or more before she can 'begin' the interview. When the interview has come to its conclusion, she may also participate in an extended 'leaving', which is absolutely necessary in this local context. Vital to the success of any interview encounter is learning about the appropriate cultural protocol and respectful engagement.

Interview Schedules and Guides

An interview schedule guides a structured interview where the focus is on consistency and efficiency or when people want to speak to a large number of folks about a particular issue. It includes both instructions for how to use it (and handle any issues that arise) as well as a set of very specific questions designed to be asked exactly as they appear. Increasingly, these kinds of schedules are being used by those who use computers in their data collection, as answers can be entered quickly (or numerically).

An interview guide is a list of questions (usually between 5 and 15), prompts or topics used in a semi-structured interview. Based on the research questions developed by the action research team, the guide is meant to help the interviewer cover areas that speak back to those questions, creating research data in the process. However, these kinds of guides will be flexible, allowing their users to change the wording, change the sequencing of topics as well as raise issues and surprises that the interviewer never planned. Although often piloted beforehand, in many projects, interview guides may change through the interviews as participants raise new issues and questions. They may also shorten or lengthen the time of an interview (from within 15 minutes to several hours) depending on how (un)comfortable, (un)safe and vocal a person is. The kinds of questions asked will also shift during an interview. Some like to begin with very general questions, such as 'How are you doing today?'. Following this, interviewers may use 'grand tour questions', such as

‘Tell me about this building’. Specific questions focus on particular events such as ‘the residents’ meeting’, and typical questions will explore general everyday events. Other questions may extend conversations, such as ‘Tell me more about the meeting this morning’ or ‘Can you give me an example of that?’. Some interviewers may bring paper and pencils or other art supplies so that they can ask questions like ‘Can you draw me a map of the community?’.

Transcriptions and Coding

Researchers have different tactics for creating interview transcripts. Some transcribe the complete interview word for word; frequently using techniques that allow for coding of pauses, silences, awkward moments and laughter, in addition to dialogue. Others, however, only transcribe what seems applicable to their own study. Transcribing interviews can be a very time-consuming process; some argue that this is best done by the researcher as it is a helpful step in familiarizing oneself with the data, while others incorporate the help of professional transcriptionists. To this end, intimate familiarity with data is not the only reason to listen to the data. Since the transcriptionist was not present during the interview, subtle meanings that the interviewer picked up might be missed. In addition, listening to the interview again provides a great opportunity to reflect on the interview process, recall details that might have been missed and potentially revise the interview guide for the next interview. Finally, listening to the interview allows the researcher to reflect on her or his strengths and weaknesses, which is especially important for novice interviewers.

Coding is a process used to organize data into smaller manageable chunks. Coding is frequently based on the theoretical underpinnings of the study, as well as the researcher’s personal assumptions about the social world. Nevertheless, it frequently follows a three-stage process. In the first phase, researchers conduct a preliminary review of the data, making notes of any ‘key moments’ where statements might be explored. The goal here is to capture simple descriptions and classifications of the phenomenon under investigation for the first set of broad themes. In the second phase, these broad themes are collapsed into descriptive codes. Following this process, a more substantive review of the data will be performed. Finally, if researchers work in a team, all descriptive codes are frequently discussed, debated and reviewed with other members of the research team before being collapsed into analytical categories that take up issues around the phenomenon under investigation.

Reflexivity

Much of conventional interviewing adheres to a language of scientific neutrality and the various techniques to accomplish this. However, in action research, the interview is never a neutral process and is always situated historically, politically and culturally as well as mediated by race, gender, sexuality, disability and a host of other identities. It follows that the interview is not merely a process of asking questions and receiving answers but a co-construction on which researchers must constantly reflect. For instance, action researchers need to ask themselves how their own positionality will affect the interviews, their analysis and the action that can result. They need to think about how their gender may affect comfort and safety, for instance, or how their privilege will shape the findings and how the context of those findings will always affect their translation. The point here is that research (work) is based on the understanding that human interpretations are the starting point to develop knowledge about the social world. How we order, classify, structure and interpret our world, and then act upon these interpretations, is always paramount to knowledge production and social change.

ISLAMIC PRACTICE

This entry explores possible connections between Islamic principles and practices and the three approaches to action research (first, second and third person inquiry and practice). There are multiple

approaches to Islam, as reflected by the variety of sects and schools of thought/jurisprudence. As such, understandings of even the broadest principles and approaches can vary.

There are many examples of the connections between Islamic thought and practice and modes of action research. This entry looks at three such examples. The focus of and practice involved in the annual observance of the month of fasting, Ramadhan, offers an example of first person inquiry and practice in Islam. Traditional approaches to the development of local sharia, or 'Islamic law', stand as an example of second person inquiry and practice. Finally, the development of an open letter from Muslim scholars to leaders and followers of the Christian faith, titled 'A Common Word Between Us and You', presents a contemporary example of third person inquiry and practice.

Islamic Practice and First Person Action Research

First person action research involves fostering an inquiring approach to one's own life, acting deliberately and with awareness of one's actions and assessing the effects of these actions on others. Various aspects of Islamic practice can be understood to actively encourage and support first person action research among observant Muslims, including the traditions and rituals surrounding the month of fasting, Ramadhan.

During Ramadhan, practicing Muslims refrain from food, drink and sexual intercourse from dawn to sunset. Those who are able to also strive to spend additional time focused on reading the Qur'an, with its guidance on matters both spiritual and practical, and engaging in additional voluntary prayers at home and/or in congregation. This month is generally seen as a time of personal purification, with a focus on reflecting on one's own spiritual state and improvement.

Numerous exhortations in the Qur'an describe people who are ultimately successful as those who 'believe and do good works' (*mun amana wa 'amila salihan*). A time of heightened spiritual awareness demands critical awareness aimed at improving oneself and one's actions. Many Muslims consider Ramadhan a month in which good deeds hold even greater value; this encourages believers to translate reflection and internal inquiry into action.

At the end of Ramadhan, all financially able Muslims are required to give a small amount of staple food items in charity (*zakat ul-fitr*), thus ensuring that all members of the community have enough food to celebrate the holiday of Eid ul-Fitr without worry.

In this way, the month of fasting ends in personal action focused on caring for one's community.

Islamic Practice and Second Person Action Research

Second person inquiry and practice revolves around working directly with others on issues of mutual concern. A thought-provoking example of this in Islamic governance is the traditional practice and development of sharia. There are various definitions of sharia; this entry will present two more common explanations.

The most common definition of sharia is typically 'Islamic law'. Sharia literally translates as 'a way'. It can also be understood as 'that which is legislated'. Muslims have some texts which legislate, most notably the Qur'an; however, the question of what each text means then arises. The Qur'an itself is the subject of many interpretive or explanatory studies under the sciences of *tafseer* (roughly translated as 'exegesis') and *fiqh* ('Islamic jurisprudence'). Understanding the texts can result in multiple voices and perspectives; most traditionally trained scholars recognize the possibility of multiple interpretations as well as their own fallibility in developing an interpretation. This plurality directly controverts the common (mis)understanding of Islamic law as a single set of rigid rules.

Sharia can also be understood as something that exists in God's mind. There are fallible ways of discerning sharia (*fiqh*), but none of the tools we have can be called sharia: They are scholars' best guesses at what sharia might be. A common problem is therefore conflating sharia with efforts to approximate sharia. The heart of Islamic law is thus a process of contestations and disputation rather than a rigid set of laws. It is a dynamic tradition of jurisprudence, including within it the recognition of the fallibility of the people and the processes involved.

Historically, the development of sharia was typically understood as a process involving both the assessment of traditional scholarly adjudications and a critical assessment of the local context. Laws were thus developed through interactions between experts in law and experts in the context. As such, Islamic laws were context specific, answering to the needs of the people and the time for which they were developed. Sharia was generally polycentric in nature, informed by overriding principles such as valuing life and protecting people from oppression. The *fatwa* literature of Islamic jurisprudence is called the *responsa* ('responses') literature because it is made up of answers to questions. These questions arise from people engaged in the context who are seeking clarification on legal issues.

Over the course of history, there have been a variety of traditions of sharia. For example, the *akhlaq* position

focuses primarily on good governance. There are also some instances of attempts to standardize laws across a larger region in Islamic history; for example, in the Ottoman context, there was a movement to ‘modernize’, making laws more standardized in line with Western polities. These laws, however, were not necessarily construed as Islamic laws or sharia.

The modern-day concept of sharia as a set of rigid rules is arguably an artefact of the colonial era. For example, in India, British colonial powers required that locally developed *hanafi* laws be standardized across the South Asian subcontinent. These sweeping changes resulted in a code of law that did not speak to each local community’s needs but was still described by the governing powers as sharia. Contemporary Islamic movements that demand a one-size-fits-all absolute ‘sharia’ rule typically ignore this pluralistic, polycentric tradition, relying on the examples of standardization that are associated with colonialism.

The traditional approach to sharia can still be found at the local level in some Islamic states where the central government is weak and power can devolve to the local level. It should be noted, however, that while the principles of sharia as context specific and responsive may still be operative, the practice of developing and enforcing local laws can be unjust or unresponsive dependent on the understanding of Islam and Islamic law held by both the scholars and the lawmakers involved.

Islamic Practice and Third Person Action Research

Third person inquiry and practice in action research involves a wider community of inquiry, focusing on processes between people who do not have direct contact with each other. Key to third person action research is both the participation of potential users in knowledge generation and the linking of concepts to observable behaviour. A recent example of this in Islamic practice is the interfaith initiative that has its foundation in a 2008 open letter from Muslim scholars to followers of the Christian faith, titled ‘A Common Word Between Us and You’ (hereafter ACW).

The ACW effort focuses on building interfaith relations and promoting peace between the two largest faith followings in the world. Although not developed as an action research effort, the processes and principles around developing and disseminating the message of ACW are generally aligned with those of third person action research. Originally signed by 138 scholars from across all major (and many smaller) sects and schools of thought, ACW presents the most extensive attempt at developing a consensus on an issue among Islamic scholars. These scholars, as representatives of their communities, met to discuss a pressing social issue:

the need to build a platform for understanding between the two biggest faith groups in the world, Muslims and Christians. Since then, over 400 scholars and leaders have added their signatures to the document.

The document makes the argument that both Islam and Christianity are based on two foundational principles: love of God and love of one’s neighbour. These principles serve as the common ground between the faiths, tying them together and offering the single most powerful argument for peace between them. The theory of the clash of civilizations makes the argument of a zero-sum game: The gain of one faith group has to be the loss of the other. The ACW directly controverts that argument, saying that both the faith groups either win together or lose together—mutual gain or mutual destruction—which is dependent on whether a framework for mutual understanding can be developed both globally and at the local level.

Over the ensuing 5 years, ACW has continued to support the development of a social movement for interfaith understanding, utilizing a variety of methods to engage local communities around the world on the principles of love and peace that lie at the foundation of these two faiths. Many communities engaging in interfaith dialogue have used ACW as a starting point for building interfaith bridges. Some of the best theological schools in the world have incorporated ACW into how they approach teaching and how they engage in interfaith studies, including Cambridge, Yale and Humboldt University in Berlin. And in 2010, the United Nations established World Interfaith Harmony Week after advocacy and diplomatic efforts by supporters of ACW from a variety of countries; the language of the resolution further reflects the principles set forward in ACW.

The 2008 open letter acted as a statement of general principles. It required local communities to determine the actual meaning of the principles in context, as well as how to facilitate them in practice. In this way, the transformation of principles into practice, while moving from a global to a local level, is an example of third person action research. Every local community must develop its own understanding of what loving one’s neighbour means. For example, in some communities, it may mean making sure that a Christian (or a Muslim) is not accused of a crime without recourse to adequate legal defence. Or it may mean ensuring that no one in the community, regardless of their faith background, goes hungry when the community as a whole has food. Thus, the final practice is dependent on the local context, while the original development of the social movement was created through expert consultation of scholars from communities around the world.

This entry has introduced possible ways of relating first, second and third person action research with

elements in the diverse Islamic tradition. Case studies and examples of contemporary action research projects taking place in Islamic/Muslim contexts have been provided in the Further Readings; these projects were not necessarily conceived with relation to understandings of Islam.

J

JEWISH BELIEF, THOUGHT AND PRACTICE

Understanding Jewish connections to action research requires a return to the roots of both Judaism and action research. Thus, this entry looks at both the legacy of Kurt Lewin, a key architect of action research, as well as ancient Jewish texts (e.g. the Torah and Talmud). It explores Jewish conceptions of text study, *tikkunolam* ('repairing the world') and *na'asehv'nishma* ('we will practice and understand'). In addition, examples of action research in scholarship on Jewish life and culture are offered.

Kurt Lewin, Jewish Life and Action Research

The connections between Jewish religion, culture and history and action research have their historical origins in the work of Lewin, social psychologist, theoretician, activist and practitioner. Martin Gold, an anthologizer of Lewin's work described Lewin's roots as a Jewish young man in early-twentieth-century Germany, where he experienced anti-Semitism and marginalization. These forces contributed to Lewin's first-hand understanding of social problems and helped drive his passion to alleviate human suffering. Lewin attended to questions of Jewish life in his scholarship, such as writing about Jewish education. In addition, in 1947, he helped establish the Commission on Community Interrelations of the American Jewish Congress, which Frances Cherry and Catherine Borshuk have described as one of the first action research organizations to be created with the express purpose of implementing community-based research to fight discrimination. The commitment that Lewin dedicated to this organization is reflected by his frequent reference to the quote by Rabbi Hillel (first century): 'If I am not for myself, who will be for me? If I am only for myself, who am I? If not now, when?' (*Ethics of the Fathers* 1:14). Lewin's

reference to traditional Jewish texts alerts us to the possibility that the connections between Jewish culture and action research may have other textual sources.

Jewish Conceptions of Text Study and Action Research

A primary aspect of Jewish life is that of communal text study. Traditional Jewish text study is rooted in a tradition of multiple interpretations, oral and written discussion and debate. This is most evident in the Talmud (a homiletic compilation produced by rabbis and sages during the Premodern Era). In this tradition, multiple interpretations from across time and space are invited to debate and discuss the meaning of Jewish law. The physical page of the Talmud reveals this hermeneutic orientation in that the focus of discussion is printed in the middle of the page, while different rabbinic interpretations surround the central text. This hermeneutic stance assumes that one interpretation is not sufficient to build a deep understanding, but rather, it is in deep discussion, debate, challenging and questioning that the learner constructs knowledge. The traditional physical space of Jewish learning, the *beit-midrash* ('house of study'), is distinctive for the pairs of learners spread throughout, studying a central text, under the guidance of a teacher. While libraries are defined by their silence, the *beitmidrash* is noted for its din of discussion and learning. In contemporary Jewish life the *beitmidrash* is still alive across the denominations of Jewish culture and across continents and age groups. In addition, debates and questions of Jewish law and ethics are still published today in the form of *response*—rabbinic responses to contemporary ritual, ethical and spiritual concerns, which are then codified.

It is such a critical stance on text, the necessity of multiple interpretations and the tradition of communal study that connect this aspect of Jewish culture with action research. As action research invites the communal construction of meaning, so too does Jewish text study.

Two Core Jewish Concepts Connected to Action Research

Na'asehv'nishma

This biblical phrase, meaning 'we will do, and we will listen/understand' (Exodus 24:7) was the Israelites' response to receiving the Decalogue and is often referred to as the root of Jewish commitment to and celebration of ritual and the primacy of ritual in Jewish life. Many interpretations of this phrase suggest that, in Jewish tradition, engaging in ritual often leads to understanding. It is action that can lead to spiritual connection, community building and deep learning. This Jewish call to action is a direct link to action research and reminds the community that while study is a fundamental aspect of Jewish life, action is also necessary.

Tikkunolam

This idea, which means 'repairing the world', of biblical and mystical origins, teaches that the world is broken and must be repaired. Strongly linked with *na'asehv'nishma*, *tikkunolam* teaches about a specific form of action—that of social change. *Tikkunolam* stresses the importance of taking positive social steps to improve the lives of people in one's community and/or the larger world. In contemporary Jewish culture, *tikkunolam* projects are ubiquitous as part of the coming-of-age ritual of bar/bat mitzvah, synagogue/temple programmes and school missions and programmes. A well-known publication, *Tikkun (Repair)*, dedicated to the mission of social change, has been part of the Jewish periodical world for over two decades. Additionally, many Jewish service-oriented organizations and high school and college programmes have been created in North America to galvanize youth towards community service.

Action Research and Contemporary Jewish Scholarship

In considering the historical and textual connections between Jewish culture and action research, we conclude with a brief comment on the place of action research in contemporary Jewish scholarship. Practitioner action research (also called teacher research, educational action research or design research) has had a strong presence in the scholarship on Jewish education and Jewish communal service, including organizational life, social work and pastoral care. Recently, scholarship on Jewish identity, Jewish issues connected to community psychology and rabbinic education has engaged in practitioner and community-based action research. Similarly, service learning has also become a centrepiece in Jewish educational contexts—from

elementary, supplementary and high school settings to rabbinical seminaries. Perhaps, it is from these settings that we may see the next generation of Jewish action research emerge.

JIPEMOYO PROJECT

Jipemoyo was a Participatory Action Research project carried out in the Western Bagamoyo District in Tanzania in 1975–9 as a co-operative endeavour between Tanzanian and Finnish scholars as part of the programme of the Research and Planning Department of the Ministry of National Culture and Youth and the Academy of Finland's Department of Humanities. Two Tanzanian and four Finnish doctoral candidates formed the interdisciplinary core of researchers representing sociology, anthropology/ethnology, ethnomusicology and geography. Marja-Liisa Swantz, a lecturer in the University of Helsinki, and Odhiambo Anacleto, Director of Research in the Ministry of National Culture and Youth, shared the leadership of the project under the general theme 'The Role of Culture in the Restructuring Process of Rural Tanzania'. The aim was to enable the villagers to realize the development potential within their cultural context while utilizing the available resources.

The participatory approach was in line with the community-based *Ujamaa* politics of the nation, in which development of people by the people was spelt out. The concepts development, *maendeleo*, and culture, *utamaduni*, were being worked out in the country under

the direction of the ruling party, Tanganyika National Union, and the Government of the United Republic of Tanzania. Jipemoyo encouraged villagers to take the initiative in solving their own problems by using their own resources (*jipemoyo*, meaning literally 'give yourself heart', in contrast to the 'trembling hearts' in the name of the town of Bagamoyo, which may have been a reference to the local slave trade).

The time was opportune for the researchers to join the villagers in common pursuit of solutions to problems as the government's nationwide programme of 'villagization' was in progress, with the aim of facilitating social, health and school services for all and using the sense of togetherness. The moving of people from scattered settlements to bigger villages on roadsides had been largely implemented in the study area while the building of houses was still in process. One issue that became central to the project was the participation of the pastoralist Parakuyo Maasai, who were being ostracized by the government staff and accused by their farming neighbours of allowing their cattle to feed in the farmers' fields, resulting in cases in the local courts. The obligatory education became another entrance point to the pastoralists who clashed with the education officers.

In terms of research, the project had tangible effects on Tanzanian development conceptions. The project aimed at making cultural knowledge an asset in the restructuring process. The research team organized a training course for cultural officers and a number of seminars, workshops and discussions in which the co-operating villagers from different sectors brought out their strengths and strains. In meeting together with local, regional and national leaders and administrators, people could experience the usefulness of the interactive and dialogical approach. Especially significant was the seminar the Parakuyo organized with the researchers for dialogue with officers of animal husbandry and political leaders from different levels. The Maasai prime minister initiated one encounter in Dar es Salaam for concerned government officers to meet with a group of pastoralists and farmers from the study area to discuss ways of overcoming the disagreements over land use. Another significant encounter was the locally organized women's seminar in interaction with village women and women officers from the district and national levels.

More important than agreeing on a theory of historical materialism or materialist phenomenology was engaging the farmers and pastoralists, men and women, in the research process, paying special attention to the women's situation and their rights within the different social groups. It was beneficial for the co-operation that the research group was interdisciplinary, as the social, cultural and political background of the people participating was central. The ethnic traditions

were identified as a product of colonial rule, seeing them as kinship-based societies in the process of gaining a national identity.

While having an impact on the formulation of culture study in the Ministry of National Culture and Youth, the project also produced a detailed collection of village-based recordings, pictures and oral and written material. All the research notes were produced in three copies (including the handwritten research notes). The total material was preserved in the archives of the ministry, in the Institute of Development Studies in Helsinki and as researchers' personal copies. Being primarily produced by the research staff and preprocessed by the archive assistants, the material is of high technical quality. Apart from describing the local setting of villagization, with its many problems, the archive is a rich collection of ethnographic material on pastoralism, music and dance, traditional handicrafts and gender issues.

While innovating Participatory Action Research methodology and pioneering in social and development studies in close co-operation with the villagers as research partners, Jipemoyo produced academically and methodologically impressive results: five doctoral theses (Kemal Mustafa, Ulla Vuorela, Helena Jerman, Taimi Sitari and Arvi Hurskainen), a licentiate thesis (Bernard Kiyenze), rich ethno-musical literary and recorded material (Philip Donner) and numerous other literary products.

Some of the concrete achievements of the Jipemoyo project were as follows:

- Bringing together administrators and struggling pastoralists into dialogue, producing concrete solutions and procedures for reconciling conflicting interests
- Making Tanzanian cultural officers aware of participation as a tool of development and cultural promotion and the significance of empirical data gathering
- Producing direct research feedback to villagers in the form of booklets, exhibitions, films and radio programmes evidencing people's participation in producing them
- Making the village-based musician-dancer Juma Nasoro an active agent of the process of his own music and dance tradition even in Finland
- Helping the government with the geographer's drawings of the new settlements

Jipemoyo has been seminal in introducing a participatory approach in development programmes, as a similar methodology using the participatory paradigm was applied later by other development research projects. The project allowed researchers opportunities for

reflection within the university circles and for contribution to international discussions on Participatory Action Research. These internal and international connections kept the politically coloured theoretical discussions going.

include details of external physical surroundings combined with an interior monologue of thoughts, feeling and perceptions. A political journal, however, is usually written with publication in mind and seeks to promote personal viewpoints and explain one’s actions. This entry maps out some of the key features of, and overlaps and differences between, various forms of journaling and points to emerging presentational formats. The entry emphasizes the role of journaling as a form of reflective practice in various contexts, arguing that its significance and value for action research lie in its potential to enable heightened reflexivity, through both the writing and the reading process, whether as the original author or as an interested, inquiring reader.

Journaling is closely linked to professional development practices in many fields of work: Teachers, doctors, nurses and social workers are encouraged to participate in reflective practice as a means of personal or staff development. Students are encouraged to maintain learning journals, the content of which might form a discussion with teachers or supervisors, forming part of a portfolio or dissertation to demonstrate development of knowledge acquisition, attitudinal change and academic engagement.

Most journals, and the techniques employed within them, are aimed at engendering some form of self-development, and in this way they vary from logs and diaries. Although the terms are often used synonymously, they have different purposes and formats.

Logs tend to be precise recordings of facts pertaining to daily operations on a regular basis. In some professions, such as aircraft piloting, the armed forces and shipping, they are a compulsory requirement, used to report on activities over a period of time. Accuracy is a paramount feature of the log as it not only provides a historical account but may also be used as evidence in disputes. Logs are also used to chart other forms of progress—for example, a student’s reading log or a research log, documenting findings at any given point.

Diaries have a more personal and intimate purpose and tone, tending to be less structured in form and internalized in their writing. Diaries often provide vital historical and social information: Sei Shonagon’s *The Pillow Book* documents life as a courtesan in eleventh-century Japan, *The Diary of Samuel Pepys* offers eyewitness accounts of the Great Plague and Great Fire of London in the seventeenth century while *Anne Frank’s Diary* has become one of the most influential documents of the Nazi occupation in the Netherlands and the effects of the Holocaust.

Types of Journaling

The journal is more purposeful than a diary, yet less formal than a log book, and is usually related to a

JOURNALING

Journaling is the practice of recording events, ideas and thoughts over a period of time, often with a particular purpose or project in mind. There are various forms of journaling using specific techniques for different purposes. For example, a travel journal might be structured around experiences in particular locations and

practice or interest. Ira Progoff, an American psychologist, developed an Intensive Journal Process, offering a system of interrelated journal processes to be followed at an individual's own pace to work through blocks and difficult situations. Progoff stresses that the process is not analytical or diagnostic but that the writing activity itself enables significant self-development and problem-solving capabilities.

Journaling in this way is based upon the idea that by putting ideas and thoughts into writing, the mind is not only freed of their recurrence, and thus the potential blocking of other ideas or activities, but the process of writing through them enables perceptive thinking and the momentum for working on them.

Reflective journals are the most common form of journaling used in professional and educational practice. The ability to critically reflect upon issues arising from one's practice, conversation or readings often generates a new understanding. Reflective practitioners and trainers such as Adams and Bolton use specific techniques such as dialoguing and clustering to aid problem-solving and decision-making, thus making reflective journaling a relevant working tool.

Research and learning journals are compiled from notes accumulated throughout a research project or study. Here, the journal acts as a record of ideas and experiences and is often reflective. It may serve as an aide-memoir, a prompt for further exploration and to record responses to readings and lectures. It is an effective means of charting the personal and practical changes and developments experienced throughout a project.

Journal Formats

Journaling implies a writing process, and for some, such as the psychologist James Pennebaker, the act of writing is central to its effectiveness as a developmental or therapeutic tool, but effective use of audio and video to record ideas for subsequent reflection offers the potential of widespread online sharing.

Artists' journals allow an especially creative way of capturing ideas and experiences that may be difficult to formulate in writing. These might include personal artwork or serve as a scrapbook of postcards, photographs or pictures from magazines or newspapers of significance supplemented with written notes or text, pertaining to the project.

Portfolio journaling further extends the capacity of the journal presentation as a source of reference for all forms of information, such as maps, films, videos, notes and observations and papers accumulated

throughout the information gathering. The format also informs the research process, enabling one to broaden the approach and remove the emphasis on the mechanics of writing where this might be problematic.

Journaling as a Reflective Process

The value of journaling in action research lies in the reflective process that encourages a deeper self-awareness and confidence in oneself through extending personal and professional insights. Ideas can be 'debated' and new approaches trialled on the page. Ultimately, journaling's value is judged on the extent to which the new awareness might be beneficial, and for this, a reflexive approach takes on importance in driving forward ideas. This circularity of action, fundamental to action research processes, makes use of the journal as a working tool and of the process of journaling as a stimulus for personal development and social action.

While journaling is considered an individualized activity, it may be effectively shared with others or collaboratively produced. Blogging, as an online journaling practice that can also be presented through visuals, broadens the scope for interaction. Electronic media and recent developments in social communications and social networking can be used to establish, share and develop new ideas and to work in globally collaborative ways.

K

KARMA THEORY

Researchers studying human actions in whatever context can either ignore or include the experiences they encounter in the context of their research. If they include them, and thus depart from a participatory research inquiry, they are required to become aware of the beliefs of the other respondents, be conscious of the given context and know how this shapes them. In this context, the focus is on karma theory. A researcher using a positivistic view will ignore karma theory because it is not objectively known (epistemology) and will use third person approaches to get knowledge, and when this approach does not verify karma theory, he or she will claim that karma does not exist (ontology). However, a researcher departing from a participatory view of research will acknowledge the epistemology that knowledge is self-reflexive; the researcher will then give room to a first person approach and, therefore, will be open to experiential knowledge which will contribute towards articulating and accepting karma theory as a part of nature, of reality, and thus given (ontology). Thus, researchers believing in karma theory and those who do not may apply different sets of assumptions and use different types of experiences, perception, interpretation and knowledge in approaching their main research concern when studying human behaviour.

There are three approaches of action research as described by the editors of this encyclopedia:

- First person research and practice skills and methods address the ability of the researcher to foster an inquiring approach to his or her own life, to act deliberately and with awareness and to assess effects in the outside world while acting.
- Second person action research and practice address the ability to inquire face-to-face with

others into issues of mutual concern—for example, in the service of improving personal and professional practice, both individually and separately.

- Third person strategies aim to create a wider community of inquiry involving persons who, because they cannot be known to each other face-to-face (e.g. in a large, geographically dispersed corporation), have an impersonal relationship.

This entry proposes that all these approaches can be preceded by encountering experiential knowledge as exemplified in karma theory—an application of a participatory world view. Such a world view is fundamentally experiential, stating that the world—here as experienced and articulated through karma theory—is the basis of ontology and epistemology. Therefore, consider the following questions: What is this Law of Karma? How does it work? How can it be applied in the context of a first person approach?

Karma Theory: What It Is and How It Works

The notion of karma has received a lot of attention in the East, mainly in Hinduism and Buddhism. It can be treated as a main ontology in Indian philosophy. The common person tends to see it as a law of ethics or a mechanism of punishment and reward governed by past actions. However, karma is not some passive mechanism but a law of action that guides the evolutionary process of individuals, families and communities. Though based on past actions, it gives full opportunities to shape the future. This requires the belief in rebirth and that past actions result in consequences in the present and influences on the near and far future. Karma means that all existence is the working of a universal energy which covers a process, an action and the ingredients of that action. The Law of Karma thus contains three parts: (1) a connection

between births, (2) a result of action and experience and (3) an evolutionary consequence related to the future. The Law of Karma has often been misunderstood. Karma is not quite the same thing as a material or substantial law of cause and effect that can be understood in the mental context of a single life. It does not work as a mechanical chain of action and consequence. It is action, and it requires a phenomenon, a doer and an active consequence. These three are all tied together so that there is an association of cause and effect, a present action following past actions and future actions following present actions.

This means that for understanding our actions and research phenomena, researchers need to relate to this energy. Humans are made of this energy; they use this energy in their actions, and thus, the effect will also contain this energy. If this is their ontology, they cannot escape this governance law, and thus, the main lesson in life is to cope with this law. How does a past karma lead to a consequence in the future? It is believed that the main mechanism here is the energy that is released when acting. Individuals release negative energy or positive energy by focusing on the ethical views of something (intellectual consciousness), how they feel about things and others (vital consciousness) and how it uplifts them (spiritual consciousness). This means that they have the power to determine their future, and thus, it is not a passive law that guides them.

For individuals, it requires a spiritual world view with a focus on two processes: first, the process of travelling through the layers of consciousness to reach subtle levels and ultimately the universal energy or oneness (that from which everything comes into existence) and, second, the process of seeking for the spirit in everything and everywhere (the spirit in which everything is involved). This requires a transformation of the inner self (inner development) and aligning it to the outer world (outer development). Both processes result in transcending interest, time and distance. It requires answering the question of who one is by seeking harmony with the inner self and harmony with the outer environment, with the result of transcending personal interest towards a broader interest (e.g. organizational or community interest), transcending time (bringing in the longer term into one's decision-making process, e.g. the new generation or all stakeholders in our research question) and transcending distance by including places that are geographically far away, which means a concern for the environment. Thus, a spiritual world view is about enlarging one's views of interest, time frame and space while constantly being in touch with one's subtle core—also in the context of doing research.

There are various concrete secular and non-secular paths to follow such a world view to deal with karma. One such path, Integral Yoga, deals with this energy in

such a way that it has evolutionary power not only for the individual involved but also for the surroundings and community he or she lives in.

A First Person Spiritual Approach to Release Positive Karmic Energy

Integral Yoga does not prescribe a clear set of practices to follow because different people have different paths based on their past karma, and even within a person, different stages in his or her life may require different tools. From the philosophy on Integral Yoga, the following principles can be applied for a first person inquiry.

Step-by-step principle: Clear out a place and time for concentrated yogic inquiry.

- Create a space in your research environment for sitting quietly to concentrate on the yogic practice.
- Place a few things to create an atmosphere that enhances concentration and sitting comfort (a cushion, a certain smell or an object for concentration).
- Keep the place set up at all times for concentration or meditation.

Regularity principle: Choose a particular time and period to concentrate on the yogic inquiry.

- Concentrate for a fixed number of minutes (5, 10, 15 or 30), preferably every day.
- If a session is missed, make up the time as soon as possible.
- Get into a routine, and stay with the routine as punctuality is needed by physical nature.

Design own path purification principle: Select any activity that helps purify energy levels.

- Read spiritual books to get in close touch with your inner consciousness. Reading is good preparation for meditation or concentration.
- Design a series of physical and breathing exercises that fit your condition.
- Talk to your inner self, or use prayers.
- Repeat specific prayers and mantras. Repeating a mantra helps quiet and control restless thoughts and enables the mind to concentrate on a simple activity. A mantra is an expression of the divine; repeating a mantra creates vibrations that are expressions of the divine.
- Contemplate planned activities and consider how to do them in a way that will help get the

most complete answer for the main concern of the research. This can be done by focusing upon the how questions (process) rather than the gains of the research actions.

- Contemplate the activities that have been completed, and consider how well they fit the research ideals and our spiritual growth, what led us away from acting up to our highest standards and how we should prevent this in the future.
- Observe your thoughts silently by listening to all the sounds around you, and as the quietness deepens, begin to hear your thoughts.

Contemplation on the karma principle: Seek unity with the cosmic law.

- Meditate on the idea of a cosmos, on you as a doer and on the active consequence of your actions in the cosmos.
- Treat material things, others, animals and everything around us well, with respect; see and feel yourself in them. This is a yogic way of looking at nature and at the world.

Conclusion

Adding experiential knowledge, grounded in karma theory, to action research approaches brings an understanding of the effect of the actions of the researcher, it creates awareness of one's self and the impact of one's actions and it provides an understanding of which elements one should focus on to release positive energy when studying a situation or context with other participants. Several principles and examples of paths have been presented. Integral philosophy states that all these principles and paths will progressively expand the practice of yoga into the normal activities of life (walking, driving, waiting in line, exercising, cooking, cleaning the house) and in professional contexts (surrendering to what happens, perceiving, listening and adapting in the research context). A personal effort is required but is not sufficient to achieve the experiential knowledge of the workings of the Law of Karma. A combination of personal effort, receptivity to the grace and action of karmic law and faith in karmic power is needed. There must be a belief that openness towards this law will create a deeper and more holistic understanding of phenomena.

KINCHELOE, JOE

Joe Lyons Kincheloe was born in Kingsport, Tennessee, in 1950. Growing up in the Deep South, he witnessed forms of social injustices based on class and race, which fuelled him to fight these injustices with powerful words and actions as a prolific yet unpretentious scholar. Influenced by blues and rock and roll, Kincheloe had a natural talent as a musician and songwriter, which led him to form a band of academics called Tony and the Hegemones, who played at many conferences and venues between 1998 and 2008. He was a Canada Research Chair of Critical Pedagogy at McGill University; he taught in the City University of New York Graduate School Urban Education Program and was the Belle Zeller Chair in Public Policy and Administration at Brooklyn College. He also taught at Pennsylvania State University, Florida International University, Louisiana State University at Shreveport and Sinte Gleska College in the Sioux Community of South Dakota. Kincheloe played a formative role in the development of critical pedagogy. His work contributed to teacher education, critical theory, cultural studies, critical constructivism, research bricolage, critical multicultural education, critical cognitive theory and critical post-formal cognition. He was the author of more than 45 books, countless book chapters, and hundreds of journal articles. He passed away suddenly in Kingston, Jamaica, on 19 December 2008 while on vacation with his partner, Shirley Steinberg, and three graduate students.

Kincheloe loved storytelling. More than anything, with the exception of football, he loved to entertain and tell stories. And stories he told. These were the most incredible life experiences told as 'Joe' stories. Those who knew him understood what a 'Joe' story was—long, detailed and somehow always filled with humour. These stories were based on the real-life experiences of Kincheloe growing up in the South and climbing the academic ladder as a White boy

with a quirky Tennessee accent. Funny, yet strange, and almost surreal stories based on a myriad of events from his young days becoming best friends with some local Italians who saved him from a street fight to the time he was stuck in a hotel elevator with a group of friends. The only consistency in his stories was the length and the incredible details; Kincheloe's stories were unforgettable—stories that a stranger would consider fictional, almost impossible.

Kincheloe's love for storytelling was a key aspect of his action research approach. He viewed his research as an ongoing conversation and created an open and safe space for everyone around to contribute and push forward ideas, theories and praxis. Most of all, he centred dialogue and discussion in his approach and facilitated the space and place for all those involved in the inquiry to contribute. His respect for indigenous ways and knowledges was the foundation of his action research, bringing forward exciting, yet challenging, questions for the researcher engaged with participatory methods. Kincheloe taught his students to always approach research with the desire to create change, to disrupt patterns and challenge environments, with a passion for transformation and social justice.

The transformative and emancipatory tenets of action research are what make it difficult and demanding. Action research is open in approach and fluid, yet demanding rigour, passion and motivation from its researcher and participants. Understood as a social process that involves participation and a collaborative effort from all the participants in the study, Kincheloe's approach involved critical and transformative efforts underlined by praxis. Due to the interwoven relationship between the researcher and the participants, too often, researchers forget or ignore their collaborators' understanding of the world and the role it plays in the research process. Kincheloe's writings with his partner Shirley Steinberg exposed the dangers of such socially constructed knowledge and emphasized the importance of participants' social backgrounds, knowledge and life experiences in the research process.

Critical Complexity in Kincheloe's Work

In an effort to bring to the forefront the diverse background of research participants and the researcher, Kincheloe's notion of action research places critical complexity as an entry point to the research method. His approach is underpinned by the performance of power which is inherent in the research process. Power is exemplified by issues of race, ethnicity, class, gender, age, sexual orientation, religion, geographic location, physical ability/disability, social actors and cultural capital. Kincheloe believed that to critically engage with research, the researcher must acknowledge the relationships among

the researcher, the inquiry and the participants, as well as the dynamics and variants that underline and surround each of these factors. If the interactions and complexity of the agents are ignored, then the researcher has failed to comprehend the reality of the participant. Kincheloe's critical action research is grounded in complexity theory and critical constructivism.

Critical complexity avoids essentialism and reductionism in action research; it encourages two-way exchanges between the researchers and the participants with whom they are working to understand the role of agency and actions/re-actions. Critical complexity also encourages new ways to understand the complications of social, cultural, psychological, and educational life and favours a holistic, inclusive and eclectic method of critical action research. His interdisciplinary ways drew from critical pedagogy, education, urban studies, indigenous knowledge, cognition, curriculum studies, cultural studies and psychology. His later work was deeply influenced by Humberto Maturana and Francisco Varela's work on enactivism, which argues that cognition and environment are inseparable and that systems learn by enacting with each other. Enactivism is centred on the notion of *double-embodiment*—things have no meaning independent of the consciousness of the agent determining meaning and are bound within a complexity system that must be acknowledged and unpacked.

During lectures, Kincheloe would often use the concept of nodes when he explained his understanding of critical complexity, drawing small, circle-like figures on a blackboard. Each node would represent a distinct 'thing', ranging from people to environmental aspects, community setting, history, geographical variants, race, class, status and so on. These nodes represent everything and anything that can alter perspectives, knowledge and relationships in research. Kincheloe explained that nodes are understood in relation to other nodes and their surrounding factors and fragments. He would always point out that what is missing is more important than what is obvious. In this context, Kincheloe explained that some nodes are so deeply embedded in environments and power structures that they can become invisible to the researcher; therefore, dialogue and reflexivity with participants are crucial to identify them and make them apparent. Thus, critical complexity facilitates this space and allows action researchers to study a phenomenon through multilogicality, which offers an observer diverse frames of reference.

Critical Participatory Action Research

Critical complexity within action research incorporates both a reflexive and a self-reflexive component in order to keep the research 'real' and 'grounded'. Self-reflexivity and group reflexivity require that

each participant and researcher address the power and social processes that are at play through the duration of the research. By engaging in a series of self- and group reflexivity processes, the researcher can truly push forward knowledge on a specific subject. This, in turn, creates an ongoing conversation between the participants and the researcher, which can change existing constructions of self and relationships with others. Critical Participatory Action Research (CPAR) helps shape the research process and outcome to allow all participants to bring forward their knowledge and opinions. Kincheloe's CPAR clarifies that it is not enough for researchers to engage in a critical complexity approach; both researchers and the participants with whom they are working must understand the complexity of praxis and how it enables a deeper understanding of possibility and a consciousness of complexity within action research. To engage in critical complexity theory means to think about the ethical, civic and socio-moral responsibilities of engaging in research.

CPAR works against notions of fixed knowledge and passive participants; in fact, it questions power dynamics and the geopolitical aspects of knowledge production, and it promotes social justice. This approach lends itself to specific attention to various dimensions of inclusion and community building for social justice. Researchers engaged in CPAR are aware of their sociocultural context and their relationships with others participating in the research.

Kincheloe's contribution to criticalizing action research highlights the importance of research that allows us to understand, acknowledge, act, react and converse—all while paying close attention to the surrounding and grounding factors of the inquiry.

Kincheloe's critical vision of PAR is devoted to a mode of sociopolitical or educational research that is aware of the assumptions that shape its purposes and designs, devoted to the ending of human suffering, focused on the consequences of its implementation and conscious of the ideological and epistemological tenets that inform it. The identification of power (political, authoritative, etc.) adds a dimension of clarity in action research that is often overlooked. Research approached in this manner facilitates authentic inquiries and allows researchers to find new levels of achievement and change previously deemed impossible.

KNOWLEDGE DEMOCRACY

It is evident throughout this encyclopedia that for a significant portion of persons using action research, the purpose of knowledge creation is as a contribution to taking on issues of injustice, inequality and oppression. This can be seen, for example, in entries such as those on participatory research, indigenous knowledge and feminist approaches. Knowledge democracy is a concept that provides a broader conceptual framework to understand the role of knowledge in the context of inclusion, social, cultural, economic and environmental justice. Knowledge democracy puts an emphasis on the links between the struggle for global social justice and the struggle for global cognitive justice.

Knowledge Democracy and Ecologies of Knowledge

Knowledge democracy is understood to mean at least three things. First, it recognizes that knowledge is relational and is represented in diverse forms, which include music, song, storytelling, sculpture, murals, theatre, puppetry, community meetings and so much more, as well as the academic forms of text, statistics and graphic representations. Second, knowledge democracy recognizes the diversity, complexity and holistic nature of often excluded or marginalized epistemologies. It recognizes the specificity of the knowledge of women farmers in Africa, of indigenous

peoples in all parts of the world, of the homeless on issues of place or those differently abled on issues of inclusion and of social movement activists of the shack dwellers movements in southern Africa. And third, it recognizes the critical role of knowledge in action to make a difference in our lives and of knowledge creation and use as a strategy for social change.

Knowledge democracy differs from similar sounding concepts of either knowledge economy or knowledge society. Knowledge economy, as it was originally intended, has been taken up by the market and the state to mean the production of highly skilled workers to fit into the global economic system of production. As evidence now shows, this is a system that is increasing rather than decreasing inequalities within our nations and amongst our nations. Knowledge society is a broader and more interesting concept that relates knowledge to issues of the state, to citizenship, and to inclusion. The literature on knowledge societies, however, largely assumes that the 'body' of knowledge that we are to work with is essentially the Western canon. The challenge in a knowledge society framework is how to make better use of already existing knowledges and processes.

Knowledge democracy is experienced at the micro and local levels, but it has aspects of global movement visibility as well. Spaces where one can see knowledge democracy at work are broad indeed. They can be seen in the recovery and revitalization of indigenous ways of knowing in Canada and in many other parts of the world. They can be seen in aspects of the 'open-access' movement for information. They can be seen in community-based organizations such as the Community Council or the Kool-Aid Society in Victoria, British Columbia, Canada, which do community-based research linked to social action. They can be seen in the work of CanAssist at the University of Victoria, where the knowledge of a person's differently abled ability is combined with technological models to create breakthroughs in adaptation for better community living. They can be seen around the world in places like Mpambo Afrikan Multiversity and the Society for Participatory Research in Asia and in hundreds of community economic development initiatives across Canada. But an additional space where knowledge democracy can be seen to be working is within the movement of community university research and engagement—a movement of the co-construction of knowledge.

In the pursuit of democratization of our societies, governments and other institutions (including universities), it is important to remember that hegemony of knowledge ('the dominant ideas of our times are the ideas of the dominant elites') is the single most powerful instrument of the status quo, since it perpetuates political authority, dominance and control. This is most critically

manifest today as corporate power and resources are financing and propagating 'new' knowledge from their vantage point; this 'corporate capture' of knowledge systems has now entered the arenas of poverty eradication and social development. Democratizing access to and control over such knowledge in the hands of ordinary citizens is becoming even more difficult in the new digital era; 'gigabytes' of knowledge stored in 'nanochips' can be manipulated by those who have the 'password' to authority—political, military and economic. It is in this scenario that the movement of knowledge democracy acquires both criticality and urgency.

Boaventura de Sousa Santos begins with his observation that in the realm of knowledge, abyssal thinking consists in granting to modern science the monopoly of the universal distinction between true and false. A way forward lies in the concept of 'ecologies of knowledge'. An ecology of knowledge framework is centred on excluded or marginalized knowledges and is based on the idea that the diversity of the world is inexhaustible. Influenced by the work of intellectuals and activists linked to the World Social Forum, de Sousa Santos feels that the global movement of indigenous knowledge has the most hope as a form of new and transformative thinking.

Knowledge Democracy in Action

Building on de Sousa Santos' recognition of ecologies of knowledge, we turn towards thinking about the use of knowledge in a strategic, organizational, intentional and active way. John Gaventa, a theoretician on power and citizenship and a pioneering participatory research leader, was the first person in our experience to speak of social movements using a 'knowledge strategy' as their core political organizing strategy. His early work at Highlander Research and Education Center in the Appalachian Mountain region of the USA involved, among other things, the support of citizen-researchers to go to local courthouses to find out the ownership of local coal mines. Absentee landlords owned all of the mines in question from as far away as New York or London. And while profits were good, taxes were very low for these absentee landlords, so that resources were not sufficient to cover the costs of good schools, health services or other social services to allow the mine-workers and their families to flourish. These citizen-researchers, using what Gaventa called a knowledge strategy for organizing, pooled their knowledge across six or seven Appalachian states and produced an important study on mine ownership, which had an impact on changing tax structures in some of the states in question. Highlander Research and Education Center and Gaventa were later to move into a campaign for environmental justice using many of the same principles.

A knowledge democracy movement is an action-oriented formation that recognizes, gives visibility to and strengthens the knowledge that is created in the context of people trying to 'change the world'. A knowledge democracy movement would recognize value and support the recovery and deepening of indigenous ways of knowing. A knowledge democracy movement would recognize the epistemic privilege of the homeless themselves as a key to taking action on issues of homelessness. It would celebrate the intellectual contributions of young people who are differently abled. It would honour the early work of Friedrich Engels gathering the insights of workers in the nineteenth century factories of Manchester, England, or Karl Marx' work in the Moselle River valley of Germany learning from workers in the vineyards. It would recognize that the gay and lesbian movement and the HIV/AIDS movements have been built fundamentally on the knowledge of gay and lesbian citizens themselves.

A knowledge democracy movement or a movement that uses knowledge as a key mobilizing and organizing strategy is centred on the lives and places of those who are seeking recognition of their rights, their land claims, their access to jobs, ecological justice and recovery or retention of their languages. Knowledge itself within such a movement formation is most likely place based and rooted in the daily lives of people, who increase their knowledge of their own contexts and, by sharing what they are learning with allies and others like themselves, move, as Paulo Freire says, towards being agents in the naming of the world. The proliferation of discourse and practices within the world of community-university knowledge partnerships, in this conceptualization, would be a contributor to the broader knowledge movement. The extensive and important access to information developments would also be supportive of and a contributor to a variety of knowledge movements. Neither the access to information developments nor the community-university engagement advancements form a knowledge democracy movement by themselves, but they would be part of the necessary conditions for knowledge movements to gain footholds and flourish.

KNOWLEDGE MOBILIZATION

Knowledge mobilization emerges from the long tradition of 'extension' work of universities and colleges into community settings beyond the boundaries of the campus. Knowledge mobilization is an umbrella concept that includes and builds on the practices described by an assortment of associated terms: dissemination, diffusion, technology transfer, knowledge translation, knowledge management, and other practices focused on spreading the results of research findings to multiple audiences and enhancing the usability of knowledge products, such as reports, papers, books, and lectures, emerging from research and assessed practice. While the term can be found in the adult education literature as early as the mid-1990s, it gained much wider use when adopted by the Social Sciences and Humanities Research Council of Canada in 2002, following the evaluation of the Community-University Research Alliance research-funding programme. Subsequent documents at this agency defined knowledge mobilization as a complex set of activities, whose overall objective is to enable those who stand to benefit from research results in the humanities and social sciences—academics, students, policy-makers, business leaders, community groups, educators and the media, among others—to have access to knowledge at a level they can use to advance social, economic, environmental and cultural development. This long definition is often shortened to getting the right information, to the right people, at the right time, in the right format, to influence their decision-making and to create new value.

The context out of which the concept of knowledge mobilization arose has meaning for the world of action research. The Canadian federal government's Social Sciences and Humanities Research Council created a unique funding window that stipulated joint community and university engagement as a requirement for applying for funds. These Community-University Research Alliance grants were an extraordinary innovation and opportunity at the time for action researchers, for community-based researchers and for engaged scholars whose work with communities consistently involved using knowledge to achieve practical and/or sociopolitical objectives. Action research calls for knowledge not only to be co-created within partnerships but also to be 'mobilized'—made active in support of the goals of the community partners.

While originally focused on extending and enhancing the value of academic research in the social sciences and humanities, knowledge mobilization has gained wider use in a range of professional practice settings—government departments, hospitals, professional associations and public service agencies seeking to gain greater value from the data and information created, at ever-accelerating rates, within their organizations. Knowledge mobilization is often referred to as a method of coping with the ever-expanding availability of data and information produced in an ever-connected world, by creating enhanced social relationships between available sources of data and information and the needs of users and decision-makers, who require it in more accessible and meaningful formats.

Socialization of Data and Information Into Knowledge

The former chief scientist of the Xerox Palo Alto Research Center, John Seely Brown, stated that data/information is really for machines; it can exist on its own and tells us something but does not recognize context and need. It becomes knowledge when it has a social life—when there is an exchange between parties to create understanding and meaning. To mobilize something is to make it mobile or capable of movement—to make it ready to do something. When an army mobilizes for a battle, it is not the battle per se but the process that readies the people, tools, machines and other resources required to engage. The same is true of public health, social justice initiatives, community projects and a wide range of value-creating activities that need to mobilize resources in order to engage in creating the positive future state at the foundation of the proposed activities.

Knowledge mobilization is not the data/information itself, nor is it the desired outcome anticipated. Rather,

it is the intermediary process that enhances and enables access to data and information to support the proposed value-creating activities. In this context, access refers to gaining both physical access to literature, databases, electronic files and other artefacts of data and information production as well as the conceptual access of understanding the utility, meaning and possible functions of the data and information in question. While physical access can often be reduced to transactional relationships—I give this to you, you give this to me—conceptual access includes more engaged social processes that require building understanding of culture, intention, benefits and possible outcomes. While some of this appears to happen 'naturally', the engagement in an explicit and managed knowledge mobilization process appears to accelerate the outcomes and produces higher quality relationships, more accessible products and increased utilization of the results of research.

Modes of Knowledge Mobilization

Large-scale studies of practice in a variety of organizational settings have shown that knowledge mobilization practice tends to fit into four modes: push, pull, linkage and exchange.

Examples of push include sending out e-mail; publishing articles, books, pamphlets and other printed materials; speaking at a conference or workshop with no opportunity for discussion or interaction; creating libraries and other repositories, either physical or electronic; creating a video for online or television viewing or creating a podcast or radio broadcast. Knowledge mobilization in a push mode makes an assumption that the intended audience will receive the message contained in the artefact. It is also referred to as the broadcast mode. It provides very little feedback on reception or understanding.

Examples of pull include creating a paper or electronic newsletter that individuals can subscribe to; syndicating a blog with an RSS (real simple syndication) feed that electronic readers can collect; following a Twitter account or advertising an event using direct phone calls. The pull mode makes an assumption that once the intended audience receive the message contained in the artefact, they will know what action should follow. The pull mode often has a feedback loop that provides data on whether that artefact has been received, but very little with regard to conceptual understanding.

Linkage and exchange tend to be tied together—it is difficult to be linked and not engage in some exchange; however, the examples below demonstrate differences of intensity and purposefulness. Examples of linkage include creating working groups,

membership in a professional association or online forum, network building and facilitation, facilitated introductions of potential research or business partners, production of a systematic review or meta-analysis that assesses multiple research and grey literature sources or any meeting, event or conference that supports potential face-to-face interaction. The assumption with linkage is that the probability of value creation increases if there is a relationship created between people. The challenge is that proximity does not necessarily lead to the creation of new knowledge and understanding.

Examples of exchange include moderating online forums, facilitating communities of practices or interactive discussions such as 'World Cafés' and moderated panels with audience participation, brokered access to customized plain-language summaries, on-call librarian assistants to answer questions in real time, multiple iterations of documents that address feedback from the audience or any number of social media platforms that allow for dialogue and deliberation. The assumption with exchange is that the complex nature of creating meaning and understanding requires ongoing feedback and adjustment. The challenge is that it favours

iterative processes that are often more expensive and time-consuming.

LABOUR-MANAGED FIRMS

All market economies are marked by the coming together of people into enterprises in order to undertake work for reward. Rewards may take the form of profits or a paying job. These organizations or ‘firms’ are marked by particular and heterogeneous cultures and socio-economic relationships. This entry first describes the classic capitalist firm and details some of the problems that they can give rise to. This is followed by an explanation of alternative forms of work organizations and some consideration as to why these are not more prevalent.

The Classic Capitalist Firm

In capitalist economies, the dominant form for the organization of firms is one where investors buy shares (or stock) and appoint managers who, in turn, hire labour in order to do the work necessary to make a profit. After paying the wages of the workers, the salaries of the managers and the other costs, the residual profit is returned to the investors as a dividend. Two important issues arise from this. First, Marxian theorists would argue that the investors are benefiting by exploiting the surplus value of the workers’ efforts. They would also argue that, under such regimes, workers become alienated from their labour. Because the firm belongs to the investors, not the people who work in it, the owners might, and frequently do, decide to transfer their capital to other cities, regions or even countries where they could get a more profitable return. Such capitalist firms can therefore have a very detrimental effect on local communities and economies. The counterargument is that investors deserve a reward for risking the capital in the first place and that they should be able to move their capital to maximize their own personal financial position because this makes markets efficient.

A second consideration is that a conflict arises in such firms between stockholders/shareholders (the principals) and the managers who are their agents. Investors appoint managers to look after their business affairs, as seen in the work of Adolf Berle and Gardiner Means. But managers are subject to a moral hazard—if they maximize the profit position of the investor, this might mean a lesser reward for their own work. Thus, they might be tempted to maximize their own financial positions at the expense of the investors. This division between ownership by stockholders and control by managers is fraught with dangers of economic inefficiency and has been the subject of much work on corporate governance (see, e.g., the work of Martin Conyon), dating back to Adam Smith.

These common types of firms engender particular socio-economic relationships marked by the expropriation of the surplus value of labour, the alienation of labour and a propensity towards the flight of capital which denies jobs to local communities. Moreover, the separation of ownership and control, and the intergroup power struggles that gives rise to, can seriously reduce the economic efficiency of firms. These firms are legitimized by supposedly objective neoclassical economic theories.

Alternatives Forms of Work Organizations

Perhaps in response to the difficulties generated by this traditional form of the firm, a significant variety of alternative types of work organization have evolved which are controlled and managed by those who contribute their labour to them. The most familiar of these are workers’ co-operatives—organizations where ownership, control and labour are at unity. Typically, all co-operative workers own a share of the enterprise and participate more or less democratically in decision-making (see, e.g., www.suma.coop). But there are other forms too. For instance, in the John Lewis Partnership in the UK, the stock of a conventional

incorporated capitalist enterprise was vested, in 1929, in a non-revocable trust, the beneficiaries of which are the current employees ('partners') and pensioners of the firm. The partners and pensioners do not own the firm—rather, it is held for their benefit in trust. They do, however, control the firm through a complex system of internal democracy (www.johnlewispartnership.co.uk). Both typical co-operatives and firms such as John Lewis have formal and transparent rules for determining members' or partners' remuneration.

These markedly different organizations, often called labour-managed firms, eschew corporate capitalist ownership structures determined by the need to access capital from stock markets. Rather, in their heterogeneity they tend to reflect the reality of the social relationships which gave rise to them. For instance, Molly Scott Cato shows that at Tower Colliery in South Wales in the UK, a group of miners made redundant when their pit closed down decided to pool their payouts in order to buy the mine and keep it running, thereby preserving their jobs. The co-op that they formed successfully sustained their local community and their families financially until the mine was physically exhausted. Because work organizations such as Tower are directly shaped by their social circumstances, they can present extremely fertile ground for the action researcher. In particular, the action researcher is afforded good opportunities to collaborate with the people who work in, and indeed constitute, the organization, rather than having to undertake research through the mediating power of management.

These labour-managed firms make complex decisions about their strategic direction. For instance, members of these organizations have to decide on the relative balance of pay levels as against numbers of jobs alongside more conventional investment choices. They also have to make decisions about the extent to which they regard the sustainability of the enterprise in local communities as important. For instance, some co-operatives have statutes that permit the hiring of staff on regular employment contracts, thereby expropriating the surplus value of their labour. Likewise, they might decide to outsource some of their functions to other countries and/or traditionally run capitalist enterprises. These organizations often go through very complex processes in order to make these decisions. Whilst there is no uniformity of outcome, it is the case that social considerations will stand alongside and perhaps even dominate neoclassical economic ones in these circumstances.

Labour-managed firms offer the prospect (but not the certainty) of improving the quality of jobs, of anchoring capital in local communities and of avoiding inefficient expropriation of organizational wealth. This raises the question as to why they remain a fairly marginal form of enterprise, with some notable exceptions such as the

Mondragón co-operatives in Spain and, indeed, the John Lewis Partnership. The answer to this question may lie in the fact that, in most market economies, capital is fairly well concentrated in the hands of a few, thereby inhibiting the start-up and development of these alternative types of firm. Beyond that, and perhaps more fundamentally, the neoclassical economic notion of the capitalist firm is hegemonic, and there may be little understanding of or skill in running these different types of enterprises. In terms of action research, they can be seen as economic manifestations of complex and varied social relationships and as having an infinite capacity for transformative adaptation and change because they embody the capacities and interests of the local stakeholders.

LADDER OF INFERENCE

The ladder of inference is a key tool of Action Science—one approach to action research. The ladder is a model of our reasoning steps as we assess a situation and decide what action to take (Figure 1). This entry describes the features of the ladder and how it can be used to help people reflect on their behaviour and the reasoning behind it.

At the bottom of the ladder are the available data: numbers on a spreadsheet, the content of a memo,

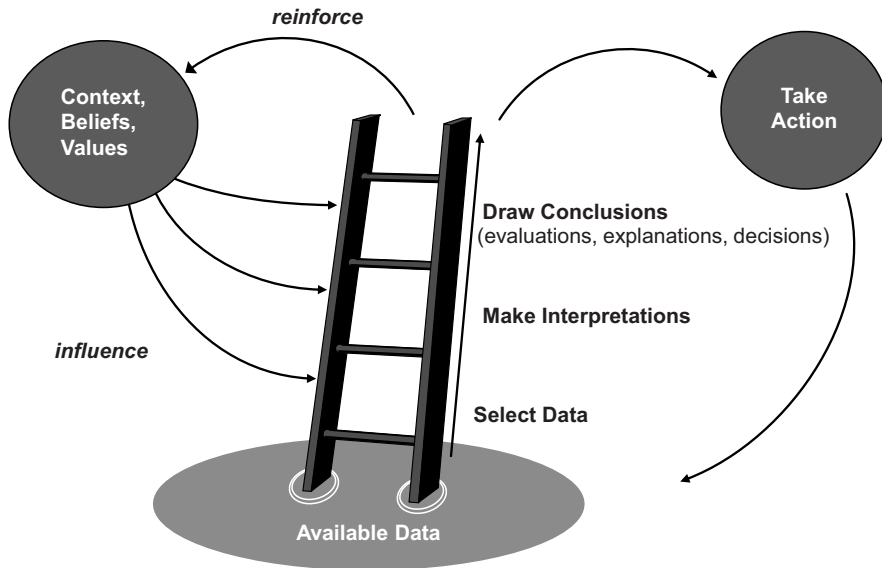

Figure 1 *Ladder of Inference: How We Think*

SOURCE: Adapted from Chris Argyris. © Action Design, 1994.

what others say, their non-verbal behaviour and so on. Given the limits of the mind, humans cannot pay attention to everything. They select, often without being aware of it, the information that is most salient and ignore the rest (first rung). Next, they interpret what that data means (second rung), and from these meanings, they draw conclusions: They evaluate, explain, make predictions and decide what to do (third rung). Based on the decisions they make, they then take action, and these actions become part of the data pool from which they draw further inferences. This is particularly important in interpersonal interaction. While they are typically aware of how others' actions affect them, individuals are often not aware of their own actions and their impact on others. Yet the actions they take become data that others use to make inferences, attributions and evaluations about them, which may be different from what those individuals hope for or intend.

Chris Argyris developed the ladder of inference as a tool for double-loop learning—learning that produces change in values and assumptions, not simply behaviour change. Initially developed for research and intervention, it is useful for anyone engaged in a difficult conversation where the quality of the conversation is critical for effective action. While there are alternative versions of the ladder of inference in the literature, all of them have a common focus and purpose: how people make inferences and the need to make inferences explicit so that errors in reasoning can be discovered and corrected.

A premise of Action Science is that any action with an intended consequence is informed by reasoning, and the effectiveness of action depends on the quality of reasoning. The difficulty with improving reasoning is that it is often invisible. Individuals 'go up our ladder' so quickly—at the speed of thought—that they are not aware of their interpretations and inferences. Their conclusions feel obvious; therefore, they see no need to check the validity of the conclusions.

How individuals move up their ladders of inference—from data to interpretations, to conclusions—is not random or accidental. Their inferences are influenced by past experience, current context, emotional state, values and assumptions. For example, in some cultures, arriving at a meeting after the scheduled start time is considered late and is reprimanded. In others, it goes unnoticed. If a subordinate says, 'We need to do X to solve Y', it is a request for resources. If the boss says the same, she is giving orders.

Much of the time, humans' ability to see larger patterns from limited data works to their advantage. It is efficient and enables them to act quickly and effectively. In routine situations, reflecting on the reasoning steps and underlying beliefs and assumptions is unnecessary. In a crisis situation, it may be impractical or dangerous. However, for novel, complex or ambiguous situations, the speed at which conclusions are drawn, assumptions are believed and only data-confirming beliefs are noticed can be a problem. While scientists are trained to test their assumptions and disconfirm their hypotheses, for most people, this

is unnatural. Failure to do so, however, can create unintended consequences. For example, a professor in a course on cross-cultural business implemented a strict 'no cell phone' rule in his class, which students frequently ignored. One day, he saw a student at the back of the class using her phone. At the limit of his patience, he strongly scolded the student for breaking his rule. The student (not a native English speaker) held up her device and said, 'I'm sorry, it's my translator'.

The ladder of inference can be used for different purposes: to reflect on emotional reactions, to facilitate discussion of substantive issues and to give people feedback. It provides a guide for effective advocacy and inquiry. The key points for using the ladder of inference to promote productive conversation and effective action are as follows: (1) be aware of reasoning steps, publicly check inferences and encourage others to do the same; (2) look for information that challenges assumptions and beliefs and (3) be aware of how actions become information that others use to make inferences.

The value of any tool depends on the attitude and skill of the person using it. Staying at the top of the ladder of inference, and stating only conclusions, is a form of self-protection. To use the ladder of inference skillfully, researchers must be open to learning—genuinely curious about others' views, willing to subject their reasoning to scrutiny and interested in discovering and correcting their errors.

LADDER OF PARTICIPATION

Community participation came into the lexicon of urban planning in the 1960s, when local governments, in collaboration with the federal government and private developers, decimated entire neighbourhoods

for the construction of freeways, hospitals and office buildings. As neighbourhoods threatened with such destruction began fighting back, academics also began criticizing the urban development models and theories that justified such top-down forms of development.

Sherry Arnstein's ladder of participation was just one of the pieces critical of non-participatory forms of development, but her use of the ladder metaphor made her model easy to popularize. Her original article is reproduced in multiple locations on the Internet, and it has spawned many adaptations. This entry will review the historical context within which Arnstein's work was developed, describe the model itself and discuss issues related to the model and its influence within many different fields of practice.

The Historical Context

In the 1960s, the US economy was strong, and large cities were transforming themselves into dispersed metropolitan areas with multiple rings of suburbs. Federal urban policy supported this population dispersal by creating the infrastructure to propel the process, including the construction of freeways and suburban housing. These policies put into motion a process of uneven urban development, as higher income residents and jobs moved outside the city and the neighbourhoods were bulldozed for the construction of freeways to move suburbanites into and out of central city downtowns each workday. Governments made promises to redevelop disinvested urban neighbourhoods, but in practice, those promises often only went so far as to tear down deteriorated houses and commercial buildings. Local governments, sometimes by requirement of the federal government, also established forms of community input where residents could supposedly review and influence urban redevelopment plans. But the processes were actually organized to allow very little influence. Plans were often created in secret and then released through a public hearing process where residents could complain but could otherwise exert little influence to change the plans. While officially termed *urban renewal*, it was increasingly known by neighbourhood residents and social activists as 'urban removal' or 'Negro removal' as the neighbourhoods targeted by the process were primarily poor and African American.

As neighbourhoods across the country, populated by residents trained in civil rights and anti-war activism, organized to resist this urban removal process, academics began building a literature critiquing the top-down biases of these urban development processes. Among these critics was Arnstein, whose background included work in the health field, a non-profit research centre and the federal Departments of

Housing and Urban Development and Health, Education and Welfare.

The Ladder of Participation

Arnstein's article 'A Ladder of Citizen Participation' was published in the July 1969 issue of the *Journal of the American Institute of Planners*. The essay was part cutting critique of the accepted citizen participation models and part an elaboration of a model of true participation. Arnstein set out a high standard for citizen participation. For her, true citizen participation involved a redistribution of power, not simply having representation in the existing power structure. Too many attempts at citizen participation, in her judgement, were ritualistic and provided nothing to the participating citizens.

This takes us to her ladder of participation. On her ladder are three sections of rungs. The lowest and most cynical rungs—therapy and manipulation—she terms *non-participation*. These are designed to get citizens to support elites' existing plans through trying to convince citizens that they, and not the powerful, are the problem. The next rungs—placation, consultation and informing—are barely better, and Arnstein categorizes these rungs as *tokenism*. In tokenism, citizens are able to get good information on the plans and are able to voice their reactions to them, but there is no mechanism to ensure that their reactions are taken into account. The highest rungs on the ladder—partnership, delegated power and citizen control—are processes by which citizens can have real influence over the actual plans and their implementation. That influence can range from a kind of joint control with government and corporate elites to full control by the people themselves.

The remainder of Arnstein's article is devoted to real-life examples of each rung on the ladder. It is important to understand that her metaphorical ladder is not meant as something to be climbed. In other words, one should not start on the bottom rung of participation and then ascend to higher levels of participation. For her, participation should begin and remain at the top. Her analysis of citizen control was prescient, promoting models that would later be found in the community-based development movement that grew across the country as successful neighbourhood resistance movements gave way to neighbourhood-controlled redevelopment planning.

Issues in Arnstein's Ladder of Participation

Looking back on it today, Arnstein's model is remarkable for its bluntly honest analysis and its willingness to make the concept of power a pivot point. Its

weaknesses—pointed out by Arnstein herself—are also important. She, of course, recognizes that resistance by elites is a problem. But she is most insightful in noting that the have-nots, if they are going to fully and powerfully participate in society, need to build their own knowledge and participation skills. Her thinking provides one of the most powerful foundations for Community-Based Participatory Research and its associated practices. These participatory knowledge practices provide some of the greatest hope for building knowledge power in excluded and oppressed communities.

It is also important to consider whether Arnstein would use the word *citizen* in her model if she were with us today. In her historical context, African American civil rights was at the centre of attention, even though there were also important Latino civil rights and farmworker organizing occurring. But the politicization of the undocumented immigrant had not yet taken hold in the American psyche the way it has today. It is possible to surmise, given the overall tone of her argument, that Arnstein would not limit participation to official nation state citizens but would advocate for a more global citizenship definition that included all those with a personal stake in a society.

The Ladder's Influence

'A Ladder of Citizen Participation' is reputed to have been translated into many languages and continues to be heavily accessed on the Internet. It is cited across disciplines and has been adapted to numerous fields of practice.

Her model has also been subjected to empirical analysis and critique. In many of those analyses, the concept of power has been taken out of the analysis, and her three distinct categories of rungs have been replaced with a continuum of participation that re-legitimizes both non-participation and tokenism processes. In contrast, Arnstein's ladder of participation made qualitative rather than quantitative distinctions between the sections of rungs on the ladder. Such qualitative distinctions lead us to think not about what power holders should do more of or less of to involve people but what they should do *differently*.

LARGE-GROUP ACTION RESEARCH

Action research is generally aimed at enabling people to address their shared concerns in a collaborative and learningful manner. Shared concerns or challenges are, however, not always confined within organizational boundaries or small groups. Ambitions to achieve impact on a larger scale than the single organization and the very nature of the shared concerns of people both lead us to address action research in large groups.

Firstly, it is futile to achieve large-scale change by changing the smaller units one after the other, due to the sheer magnitude of the task. For instance, the need to improve the innovative capacities of a region's companies may not be achieved by changing the single companies one by one. There is also no direct diffusion of learning and change from one or a few cases to many cases, neither directly between practitioners without mediating processes nor via general theory. Hence, we cannot rely on theory production alone or on word of mouth to create a societal or large-system impact. Action research therefore needs to encompass learning mechanisms, change and knowledge production that reflect the whole system that needs changing.

Secondly, the shared concerns and the problems or challenges facing people and communities are often of such a complex nature that they call for participation of a larger stakeholder set in order to be improved upon. Such issues may often be perceived as part of community or regional development, such as youth crime, unemployment, environmental issues, racial conflict, urban regeneration, industrial development, the tourist attractiveness of a location and so on.

In this entry, addressing 'large groups' is taken to imply efforts that reach beyond the single organization or the small group with its face-to-face relationships. The entry will emphasize the challenges of doing action

research in large groups, including the importance of understanding the system and who is in it, establishing a legitimate position for the researchers and organizing dialogical processes that lead to joint action.

Characteristics of Action Research in Large Groups

Issues and challenges in doing action research take on a new dimension as scale and complexity increase. The wide range of constituents creates an increased diversity of interest, perspectives and knowledge, and the number of potential participants itself makes it more demanding to bring people together in dialogical processes. In dealing with complex issues that cross organizational boundaries, power and systems of interest move to the foreground. Action research must therefore understand the power play and systems of interests *sufficiently* in order to engage all relevant actors in ways that encourage joint learning and action. In doing so, the action researchers need to establish a legitimate platform for engaging with the system; this is often an act of balance. In order to handle the magnitude of the task, building an action research team becomes part of doing large-scale action research. These issues are explored further below.

Challenge 1: Understanding the System

As the action researchers approach a new large-scale research field with a rudimentary understanding of the problem complex, the first issue to address is to establish an understanding of the system at hand. Initially, a preliminary stakeholder mapping is warranted in order to identify who the key actors are, who are potentially affected and who can potentially affect the outcome, and, hence, who should be involved in the action research process. As the understanding of the complex issue at hand matures, this question has to be readdressed, often several times.

Because large-scale projects most often cross organizational boundaries and involve a larger stakeholder set with different interests, competencies, perspectives and relationships, the next crucial issue to understand is the nature of power relationships and systems of interests. Collaborative change inevitably challenges power and formal decision-making systems. For action to happen, the action researchers need to know who the final decision-makers are, how they relate and what constitutes legitimacy in this particular field. Not a full, but a sufficient, understanding of these power relationships is needed in order to assess the potential for action, negotiate openings for collaborative approaches where power is balanced as well as address the issue of the powerless or unorganized and how to give them an adequate voice in the process.

This mapping phase, which should be prior to bringing people together in dialogues, may well be approached by interviewing key stakeholders to understand their perspectives, interests and relationships. In sum, this provides a richer understanding of the issue and its actors than each of them has, often to their surprise. This knowledge needs to be shared and validated and may lead to an increased recognition of the legitimate right of the others to participate, a better understanding of the complexity of the issue and a recognition of the need for collaborative processes and legitimate joint actions.

Challenge 2: Establishing a Legitimate Position for the Researchers

The role, mandate and legitimacy of the action researchers in a large, multi-stakeholder research field need to be addressed consciously, from the outset and throughout the project.

The first important question to address is who the client or partner is. Who the client or partner influences how the researcher's role is perceived, the room for manoeuvring one may get and the legitimacy base for engaging with the system. If the client is only one of the stakeholders, the researchers may be taken to represent only one view or set of interests and may be taken 'hostage' in the ongoing power play. This will severely hamper the possibilities for moving the field forward in a collaborative manner.

To provide the necessary legitimacy to move between the actors and take initiatives, the client construction should reflect the main stakeholder set of the system to provide a legitimate, power-balanced platform. Frequently, the main stakeholders have formed a Development Coalition or other form of collaborative unit reflecting how the problem complex is perceived. In other instances, it may be possible to influence or negotiate the client construction, for instance, by forming steering committees or other collaborative bodies.

When a sufficiently broad client structure has been established, the action researchers need to manage the typical expectations that they are (a) experts and hence should provide the answers and solutions, (b) useless in practical terms and not really needed or (c) given only fact-finding functions and not brought in to address the whole system.

In order to overcome these expectations, the action researchers often have to earn the trust of the stakeholders, which may not be given to them at the outset. Trust develops through experience and may be achieved by demonstrating over time how they handle sensitive information, how they demonstrate understanding of the issues and the system, how they

manage processes and how they are able to balance different perspectives.

Challenge 3: Design and Implement Participative Processes

Action research in large groups will seek to develop participative processes based on dialogue where inquiry, learning and joint action are integrated.

A key role to play for the action researchers is to pay close attention to who are included and excluded in the development processes and to find ways to include all the affected actor groups. Marginalized or ignored groups may need assistance to organize their ability to voice their perspectives. Depending on the problem complex, groups that may easily be overlooked could include workers, youth, women, elderly people and the handicapped, but more powerful actors may be left out initially because the issue at stake has been poorly conceptualized.

The action researchers will attempt at co-designing the processes with the stakeholders in order to create learning and ownership and to develop sensitivity to the specific context and its politics. This may be tricky when the stakeholders expect an expert role. Differentiating between being experts in co-design and being an expert in expert design is the pivotal point.

The challenge of constructing and reconstructing arenas for dialogue between a large number of people has led to the development of two distinct forms of conferences—the Dialogue Conference and the Search Conference. These may be used with 20–80 participants, each built around a specific logic, alternating between dialogues in small groups and a plenary session. In larger systems, it may be necessary to link several dialogue or Search Conferences, both in parallel and in sequence, with workshops and other meetings in order to bring forward different voices and arrive at an agreed-upon set of actions.

For the dialogic learning process to lead to action, the stakeholders need to create a referent organization to carry out whatever plans and decisions the participants have made. Preferably, the referent organization emerges out of the conferences or the process, or it is designed earlier as a legitimate body to take on action on behalf of the constituencies. The referent organization may have the form of a secretariat, an agency, a working group or the like.

LEARNING HISTORY

Learning History is an action research approach to capturing the learning from a project, initiative or event in a way that emphasizes the human experience of those involved and via a participative process that is devised to stimulate wider learning from those experiences. A Learning History is therefore both a product and a process. The product is the story—told through the voices of those involved and mediated via the reflective thoughts, questions and analysis of the researcher. It is co-produced between outsider researcher and insider protagonists. Typically, a Learning History takes the form of a written document, often divided into two columns, whereby original, verbatim quotes from the protagonists are woven together with researcher reflections and narration. Together, this counterpoint is often termed a *jointly told tale*—a term borrowed from ethnographer John van Maanen—that charts a reflective history that in its presentation is intended to stimulate further reflection and inquiry.

The history product then forms the centrepiece of a learning process that splits into two parts. During the co-creation of the history, the attention is on the learning that those involved in the original initiative derive from voicing and reflecting on their story. Post-production, the attention moves to consider the learning that can be derived more broadly from the history itself. As a quick shorthand, a Learning History is sometimes described as the action research version of a case study. This is a helpful analogy but can also be misleading. It is true that the production of a written Learning History draws on standard qualitative research approaches—for example, semi-structured interviewing and Grounded Theory—more than other action research approaches. However, the emphasis of a Learning History on story and in particular on the vivid detail and personal voice of those involved is fundamentally different from a case study approach, which emphasizes a more generalized, abstracted description. Similarly, the tighter relationship between the history and the process of learning in which it is embedded differs considerably from case study approaches.

Origins of Learning History

Learning History was developed first in the early nineties at MIT's research centre for organizational learning (which later went on to become the Society for Organizational Learning). The idea of the 'learning organization' as an entity with the capacity to learn effectively and hence to flourish had been popularized through the work of Peter Senge and others at MIT. Their text *The Fifth Discipline*, and its associated field book, had a wide appeal to management practitioners and academics alike. However, the link between learning and business success remained tenuous. Could learning be claimed if it wasn't clear what lay behind good or bad practice, successes or failure? It was in an attempt both to clarify how learning occurred and to stimulate it more widely that Learning History was conceived. It was, in part, a response to an imperative for evaluation and also for a different kind of experience-based learning.

Though working in the management learning field and situating themselves clearly within the Action Science tradition of Chris Argyris and Donald Schön, the originators of Learning History, Art Kleiner and George Roth, took wider inspiration from the age-old practice of oral history. Looking to this and recent works of social history (e.g. Studs Terkel's oral history-based stories of America), they set the ideas of oral history—listening, voice and story—at the heart of a research process. The emphasis on personal story is crucial to Learning History. It brings specificity,

detail and feeling and so surfaces that which is tacit. As the cognitive psychologist Jerome Bruner writes, narrative deals with the ‘vicissitudes of intention’. An oral history will describe the ups and downs of experience, the changing fortunes and moments of doubt and reasons for action caught in a moment of time. These are unique but also universal in their way. It is by staying close to these specifics of experience that Learning History is attempting to get past what Roth and Kleiner called a mere listing of ‘best practices’ and into ‘the thinking, experimentation and arguments of those who have experienced the same situation’.

Early Application

The first Learning History was conducted by the MIT team in the mid nineties at an automobile manufacturing company with the pseudonym ‘AutoCo’. This followed the experiences of a team leading up to the launch of a new product. An edited version of the resulting Learning History was published in 1999 in Roth and Kleiner’s book *Car Launch: The Human Side of Managing Change*. Through the nineties, a number of learning histories were reported by the MIT team to have been conducted in a range of corporate settings. Two histories charting successful business transformation at the consumer products company Unilever and at an anonymized oil company were published as books. Further histories were created at telephony and electronics companies. By the late nineties, Learning History was being taken beyond corporate settings to the not-for-profit and educational sectors. In 1998, for example, Hilary Bradbury co-created a Learning History with the Swedish environmental charity, the Natural Step. And in 2001, Rupesh Shah developed an inter-organizational Learning History with Shell Oil and the international environmental non-governmental organization Living Earth to explore the contentious issue of environmental damage in the Niger delta. Shah’s work brought Learning History to the Centre for Action Research in Professional Practice (CARPP; see also the entry ‘Centre for Action Research in Professional Practice’) in the UK.

Drawing on the AutoCo and other early Learning History projects at MIT, the *Learning History Field Manual* was developed and first published in 1996. This set out in detail the recommended form for a Learning History as well as the steps involved in producing one. The principles and methodological steps set out by this early work established a trajectory for Learning History that sustained over time. Over the subsequent decade, Learning History started to emerge as a genre where each instance, though situated and context dependent, shared a number of recurring characteristics and methodological principles.

Learning History Characteristics, Method and Form

Characteristics

The following are five key characteristics of the Learning History process:

1. *Tangibility—the Learning History centres on tangible events*: A Learning History charts that something tangible, past or present, has occurred. This provides the storyline that ideally is situated within an agreed time frame. Some Learning History projects explicitly start with tangible outcomes or success and chart how these came about. Others track a particular project initiative as it unfolds. Focusing on a tangible achievement or a time-bounded event means that the participants are better placed to ground the history in their personal experience.

2. *Co-production between insider and outsider researchers*: The collaboration between the insider and outsider research team to co-produce the history—often called the ‘jointly told tale’—and guide the associated learning process is a key characteristic of Learning History. Throughout the process, the insider protagonist and the outsider researcher have distinct and differentiated roles bringing different skills into play.

3. *Multi-stakeholder involvement—participation at all stages of the process*: The production of a Learning History is embedded in a participative process that explicitly seeks to draw out multiple perspectives so that hidden assumptions and taken-for-granted storylines can, through the process, be challenged. From design to dissemination, stakeholder involvement is actively sought.

4. *Polyvocal story centring on the voices of those involved*: The Learning History reproduces the words of the insider protagonists and thus places primacy on their original voice, style and idiom. In this way, it centres on subjective experience and further seeks a polyvocal account whereby multiple voices are represented. It is in the contradictory fault lines between individual stories that often the rich learning opportunities lie.

5. *Parallel research process*: Learning History production generally includes a rigorous research process whereby the interview data set is distilled for key themes, storylines and illustrative quotes. Thematic work often follows more standard qualitative research approaches—for example, Strauss and Corbin’s approach to Grounded Theory. These themes are then woven into the resulting Learning History either

explicitly or implicitly. Roth and Kleiner highlight the importance of cycling between the data and the story (they call it the ‘research’ and ‘mythic’ imperatives) in order to keep the resulting Learning History ‘honest’.

Method

There are a series of distinct stages in the design of a Learning History project. In the literature, these have variously been combined to suggest between four and six stages. Table 1 outlines five stages, where the first four stages relate to the front-end production of the Learning History and the fifth relates to the back-end, post-production learning stage.

There are many choices and varying degrees of freedom in each of the above stages. For example, the way research projects are commissioned might mean that the planning stage cannot involve as many stakeholders as might be desired. Similarly, during distillation, the question of whose purposes are being served will drive how the Learning History is produced. For example, a Learning History for an academic thesis will have different exigencies during distillation than a

history that is explicitly commissioned for the purpose of organizational learning. At each stage, learning historians must balance pragmatic considerations of budget, resource and politics with the participative and pluralist principles underlying the approach.

Researchers have themselves variously interpreted the degree of co-production and participation in a Learning History process. Learning histories often can end up being crafted or written by outsider researchers. Similarly, validation can sometimes be interpreted as a stage of checking and ‘sign-off’. In contrast, it can be a key stage of collaborative learning where different stakeholders are brought together to share their different reactions and perspectives on the history that has been created.

Open System Method

It is worth noting that the final post-production stage, ‘wider learning’, has until recently been underplayed in the Learning History literature. This stage is often referred to as ‘dissemination’, suggesting that once the history is written, the model

<i>Number</i>	<i>Stage</i>	<i>Description</i>
1	Planning	Insiders and outsiders come together to co-design the project. Multiple stakeholders are invited to negotiate the storyline and the range and scope of the history. An insider/outsider ‘learning historian’ team is set up. This stage culminates in the identification of insider protagonists, and an invitation to interview is issued to them.
2	Data gathering	The main data-gathering stage. Learning historians conduct reflective one-on-one interviews or sometimes group interviews that are recorded to provide verbatim quotes. Additional material from company documents and websites may also be gathered at this stage.
3	Distillation and production	Recorded data is usually transcribed and distilled for key (a) storylines, (b) themes and (c) illustrative quotes. These, together with any background data, are crafted into the chosen Learning History form where thematic, narrative and insider voices are placed side by side.
4	Validation	A draft of the Learning History is shared with those who contributed. Validation can occur on an individual or group basis.
5	Wider learning	The back-end stage, where the agreed Learning History is now taken more widely to support wider learning—either within the originating organization or further afield. Sometimes termed <i>dissemination</i> , this stage has more recently been interpreted as having significant potential for system-wide learning by taking a more participative approach to it.

Table 1 *The Five Stages of a Learning History Project*

for propagating the learning from it reverts to more conventional and non-participative styles of learning—for instance, presentations and circulation of the ‘document’. In recent years, questions of deriving broader, future-focused and actionable learning from learning histories have come to the fore, and this has led to more interpretations of Stage 5 that are proactive and focused on learning beyond the originating organization.

One key example of this is the Lowcarbonworks action research project at CARPP, funded by the Engineering and Physical Sciences Research Council and the Economic and Social Research Council (UK Research Council), which applied a Learning History methodology to the inter-organizational and sectoral level, with a view to understanding better the complex systemic issue of low-carbon change. On this project, over a dozen learning histories were created across the private and public sectors. Focusing on UK local authorities and successful low-carbon initiatives that had occurred there, Margaret Gearty’s doctoral work articulated a new form of Learning History—the Open-System Learning History, where multiple learning histories fed a series of varied ‘learning events’. Far from being passive, then, Stage 5 was conceived as proactive and engaged, bringing multiple stakeholders together in different learning communities.

Form

In the decade following the first Learning History at AutoCo, a distinctive Learning History form has become established. At its heart is a written, two-column format whereby insider protagonists’ interview quotes on one side converse with researcher reflections and narration on the other. The two-column format was not a Learning History invention but drew inspiration from the earlier work of Argyris and Orlando Fals Borda, both of whom had experimented with the two-column format much earlier as a means of supporting reflective learning. Fals Borda reports using the format in his community development work in Colombia as far back as the seventies. The two-column format creates a dialogical text whereby the reader is invited via the experiences of the protagonists, and the reflections of the researcher, to reflect the history and relate any learning to his or her own context.

The two-columned format then sits within an overall presentational form that has varied from project to project. The AutoCo Learning History, for instance, was a 90-page document that was structured into six themes, with each theme illustrated with a two-column presentation. The right-hand column told the story in the words of the participants. This material was drawn from the primary research data. The left-hand

column contained the voice of the researcher, providing interpretive material and drawing attention to questions, analysis, implications and so on that came out of this material. Further framing, explanation boxes and background information rounded out the document.

In his analysis of the Learning History genre in 2007, Steve Amidon noted the appearance of more standard reporting devices such as abstracts, executive summaries and conclusions in a number of Learning History documents and points to the prevalent managerial need for summaries and outcomes as potentially being at odds with the goals of creating dialogue and reflective inquiry.

Emerging New Forms

By 2009 and in the context of the Lowcarbonworks programme, the distinctive, two-columned written form was itself called into question. In her doctoral work, Gearty suggested that the dialogical quality of Learning History could be achieved in a number of ways, and indeed, these were not confined to written media. Her set of written learning histories interspersed quotes, photos, themes and theoretical links in bubbles and boxes around a core, time-bound narrative. She proposed that digital and dramatic forms of Learning History might be equally valid and indeed more appropriate in certain settings and therefore worthy of consideration. Dramatic and artistic forms of Learning History were then further explored in the context of Lowcarbonworks, and these experiments in turn inspired further research projects at CARPP and elsewhere that had lighter and often more flexible forms of Learning History at their heart.

Learning History and Action Research

Learning History is a particular form of action research. The centrality of the research output—the Learning History—distinguishes it from other, more process-driven kinds of action research. Though still fundamentally participative, the process is also more differentiated in terms of ‘insider/outsider’ skills and roles. The ‘outsider’ researcher(s) draws on standard research methods—interviewing and thematic analysis—more so than other forms of action research, where outputs are often more provisional and emergent. The structuring of the collaborative inquiry differs also from other forms of second person action research. In Learning History, inquiry occurs in relation to the story that is being created or that has been told. This contrasts with Co-Operative Inquiry, for example, where inquiry evolves in relation to the practical issues and concerns of the participants.

Recent developments in Learning History research discussed above have recognized the catalytic nature of Learning History within the wider system and so open it up as a piece of third person action research. The open system Learning History places the 'artefact' at the heart of a learning process that extends outwards to include face-to-face inquiry, but that can also, in its way, speak for itself in a third person context.

Trends in Learning History Research

Learning History continues to appeal to researchers and organizations as an approach, though it does not appear to have been widely applied. Amidon's survey of Learning History in 2007 turned up just 12 published instantiations. However, there may be many more. Learning History practice is often located on the boundary between research and consulting. Given their often proprietary and sensitive nature, many learning histories are not in the public domain or documented in the academic literature. This makes the extent of Learning History application hard to assess and the methodology itself hard to progress, but it is fair to assume that it has not been widely adopted. Learning History requires time and resources. It asks for the space to be made for reflection where fast-paced organizational life is generally set up in the countervailing direction. The resource-intensive and rigorous nature of early Learning History forms has no doubt contributed to this, and recent trends to work with lighter, flexible forms might to some extent counteract this, though not entirely.

Going forward, there are many interesting trends in Learning History. With the loosening of form, links to the emerging field of arts-based action research are starting to be made. Systemic work with Learning History is also an emerging area, and Lowcarbonworks is but one possible interpretation. In her unpublished work with a global religious community, Paula Downey has combined Learning History with a living systems perspective in an exciting way. In this work, a small 'insider' group was facilitated over an extended period to harvest and distil conversations and experiences from across the community into thematically based learning histories. By 'listening' closely to the many different voices and experiences of others, and reflecting together on these, the 'insider' team found that they gained deep insights into the nature of life in their organization and its development needs at that time. The process was experienced as profoundly transformational on a personal level for some members of this team, simultaneously contributing to their leadership development and greatly enhancing the

capacity of the small group as influencers in the wider system.

This suggests that sustained, actionable learning from Learning History can be derived in many different ways as the dance between product and process continues to be explored.

LEARNING PATHWAYS GRID

The Learning Pathways Grid (LPG) is a visual template (see Figure 1) for a particular kind of conversation analysis. LPG analysis helps professionals discover links from cognition to action, to the effects of action and makes those links explicit; it then supports a pragmatic redesign of action. LPG analysis is a powerful action research tool. It allows professionals to develop reflective practice skills in a rigorous, structured and collaborative way. While 'reflective practice' may appear mysterious and unattainable, the LPG allows practitioners at any level to identify ways in which their espoused beliefs and actual actions conflict or are in sync, a key reflective practice skill.

An LPG analysis is a stepwise process of reflection which guides inquiry into past conversational behaviour that has yielded undesirable results. It is done in a group. At each step in the LPG mapping and redesign, respectful inquiry and suggestions from group members can help an individual see past her or his inevitable biases and blind spots and empower the individual to adopt a new, more effective approach to a challenging situation. At the root of LPG analysis is the *frame*, a term applied loosely to encompass related concepts such as assumptions, cognitive schemas and mental models. The simple LPG conceptual model is that frames lead to behaviours, which in

turn have consequences, as depicted by the left-to-right sequences in Figure 1. Frames both inform and limit actions; however, the individual has the power to imagine and adopt different frames that will lead him or her to more effective behaviours. LPG analysis supports this reframing. The LPG emerged from the interrelated traditions of Action Science, organizational learning, action inquiry and family systems therapy. It was developed initially by Diana McLain Smith and colleagues in the early 1990s for use in organizational development consulting. This entry explains the LPG and describes its application.

LPG Analysis Overview

LPG analysis begins with a case written by an individual whose actions failed to yield the desired outcomes. The focal behaviour is excerpted from an interpersonal interaction, which might be a meeting, a teaching or training session or a professional team effort, such as surgery or the work of a flight crew. LPG analysis is conducted 'offline' with trusted peers. The remainder of this entry refers to those conducting the analysis as 'the group' and to the focal individual who experienced the dilemma as the 'case writer'.

LPG analysis follows the flow of the arrow in Figure 1. The case writer prepares a case about a conversation with problematic results. The case is presented to the group. The group and the case writer then use the LPG to map specific thoughts and actions that appear to have led to the undesired results. Group and case writer then use the LPG to craft alternative ways of thinking and acting, which hold the potential to bring about the desired results in the future. The steps are described below.

Case History

The history is typically brief. It includes specific examples of what was said and done, how others responded and what the focal individual was thinking and feeling. The case also includes a brief introduction with some background and ends with lingering concerns or questions.

Mapping Problematic Thoughts and Actions

A blank LPG (Figure 1) provides a sequence for and visual record of the analysis. A highly simplified case is used in the following example to illustrate the six steps of the LPG analysis. In this case, the case writer had grown frustrated and quit a project team when the team appeared to be mired in old habits and when the team members appeared unwilling to listen to the case writer's suggestions.

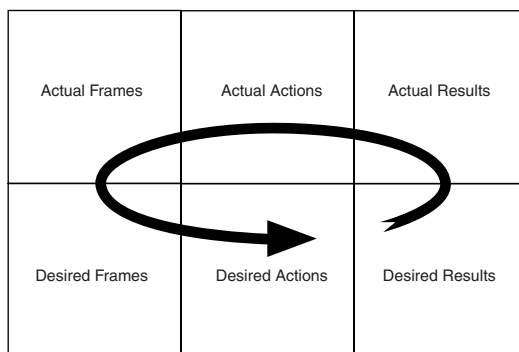

Figure 1 *The Learning Pathways Grid*

SOURCE: Adapted from Smith, D. M., McArthur, P., & Putnam, R. (1993). *Organizational learning in action*. Weston, MA: Action Design. Available at <http://www.actiondesign.com>.

1. In dialogue with the group, the case writer first enters one or more items in the Desired Results LPG cell to document his aims for the interaction described in the case. Two desired results in the sample case might be 'Team learns of problems with current methods' and 'I help team envision new methods.'
2. Next, the group documents Actual Results—in other words, the problematic outcomes. For the sample case, this would be 'Team maintains current methods' and 'I quit the team'. Comparison of actual with desired results yields an outcome gap—that is, important ways in which the results differed from the aims.
3. The group identifies Actual Actions, for example, what was said or left unsaid, which led to the Actual Results and, in particular, to the outcome gap. For the sample case, this would be 'I explained why their approach is wrong', 'I said they seemed unwilling to listen to my ideas' and 'I quit'.
4. In the next step, the group helps the case writer uncover the subjective experience leading to the actions and to the outcome gap. Typically, this centres on the case writer's thoughts and feelings leading to the actual actions and, more specifically, on the case writer's often tacit assumptions or patterns of beliefs, called 'frames' in this context. For the sample case, this would be 'The team is stuck in habitual practices' and 'The team will never listen to a new employee like me'. While a wealth of accurate frames often can be generated at this stage, the analysis should be parsimonious: What are the most essential and powerful frames that can explain the Actual Actions?

Crafting Alternative Ways of Thinking and Acting

With the problematic thoughts, actions and results mapped, attention turns to reframing and the situation.

1. The overarching inquiry here is what plausible new perspectives and/or assumptions might the case writer adopt which could lead to more effective actions and desired results? The aim is pragmatic: What are the simplest, subtlest cognitive shifts that can trigger more effective actions? These are entered in the Desired Frames LPG cell. Continuing our sample case, this would be 'The team's current methods may actually be logical; the better I understand the team's current methods, the better I can suggest improvements that members will accept'.

2. Finally, the group helps the case writer generate some potential Desired Actions consistent with these frames, which may help the case writer achieve the desired results in the future. To conclude our example, 'Inquire about the logic of the team's approach', 'Avoid attacking their approach', and 'Suggest improvements that build on what they are already doing'.

LPG analysis is most useful when the type of situation analyzed is likely to recur and where the case writer's actions are likely to affect the outcomes in meaningful ways. It can be used anywhere when individuals wish to learn from interpersonal experience in order to improve their professional or personal practice and where they have a trusted group of colleagues or peers to work with.

LEARNING WINDOW

Action research involves practices of living inquiry intended to generate conditions for change in systems with others. Curiosity, engagement and question posing are brought to bear on shared concerns with the intent of learning to make change over time. The methods of learning within an action research project are numerous, including engaging with cycles of reflection and action, explorations of systemic conditions for change as well as individual and interpersonal capabilities to collaborate and diagnose the systems readiness for change. One such method for a better understanding of what is going on within a system in relationship to

a perceived organizational concern is the learning window. The learning window is a learning tool that directs inquiry from four specific perspectives to look into a system for deeper understanding. This tool directs the attention of individuals to diagnose both what they presently understand about an organizational concern as well as what remains to be discovered.

Lyle Yorks developed the learning window as an adaptation of the Johari window, a technique created by Joseph Luft and Harrington Ingham in 1955. It was used to help people better understand their relationship to self and others. Like other feedback mechanisms, the Johari window has been a useful tool for giving and receiving feedback about individuals' and groups' actions within a system. Four windows bring attention to self-awareness and other awareness. Two of the four windows pose questions that increase self-awareness of themselves as actors in systems and the impacts of their behaviours. The other two windows increase awareness of unconscious impacts of the self on the system. Used as a heuristic exercise to increase self-awareness and group awareness, this tool has been adapted into what has come to be known in action research methodologies as the learning window.

As a tool for inquiry and learning, Yorks specifically developed the learning window as a structure to focus attention on simultaneous awareness of individual and collective knowledge of a system. A system refers to what David Bohm described as a set of connected things or parts. The way people use the word now, it means an entity all of whose parts are mutually interdependent—not only for mutual action but also for their meaning and existence. A system is constantly engaged in a process of development, change, evolution and structure changes. Understanding a system as complex and interconnected requires an equally complex learning method. The learning window initiates a process of better understanding the interconnections among systems through four distinct perspectives.

The learning window asks four critical questions regarding knowledge and discovery:

1. What do we know?
2. What do we think we know?
3. What do we know that we don't know?
4. What might be outside our conscious awareness? What are we currently blind to that might have an impact on this issue?

The fourth window is an invitation to discover from the unexpected, emergent and spontaneous. In service of practical knowing, the learning window

provides a structure for participatory processes concerned with developing knowledge in pursuit of worthwhile human purposes. Such a learning structure emphasizes the skilful means required to bring together action and reflection, knowledge and discovery, in the pursuit of practical solutions to pressing issues in communities and organizations.

Each of the perspectives provides insight into the system's current reality and a common ground from which to launch the activities of action research. The first window invites the first person subjective perspective of the researchers—for example, what 'I' know to be true about a perceived shared concern. The second window inquires into the collective intersubjective knowledge of the group—for example, what 'we' know about each other and how we understand the presenting concern. The third window is a line of inquiry to identify and describe the objective artefacts of the organizational concern—for example, illustrations of how decisions affect the intended outcomes, processes, protocols and policies that signal a misalignment between intention, action and outcomes. The final and fourth window opens space for possibility by welcoming what is unknown and what could emerge if conditions were ripe and ready—for example, an awareness of what remains unseen and unknown that makes way for discovery, transformation and innovation to emerge.

The learning window is often utilized early as a learning strategy during action research cycles of reflection and action. It is a tool for exploring how to learn together about possibilities that catalyze change. In addition to helping understand a shared concern from multiple perspectives, the learning window also makes visible what at times is unseen, in the shadows and blind spot of individuals, groups and systems.

Action research is an evolutionary process, emerging developmentally over time as individuals develop the skills of inquiry, and communities of practice develop within systems to produce practical knowledge. Though learning structures such as the learning window provide a framework for engaging in inquiry and reflection, action research is an emergent process that lets change come in the doing of it. In this sense, the learning window allows for practical (usable, timely insights) knowledge to be validated and/or put into question. This in turn allows shared awareness to emerge in the action of inquiry.

LEWIN, KURT

At the time of his death in 1947, Kurt Lewin was considered one of the most important figures in modern psychology. He was the first to coin the term *action research* and specify its major components. According to his definition, action research is comparative research on the conditions and effects of various forms of social action. In Lewin's view, this is the kind of research needed for social practice. The idea of action research was the last topic that engaged Lewin's attention prior to his untimely death.

In this entry, some highlights of Lewin's biography will be presented, followed by a discussion of Lewin's 'field theory'. Emphasis will be placed on explaining the meta-theoretical principles and values underlying field theory, which are the cornerstones of action research. Lewin's theory of social change and the components of action research will also be explained and discussed.

Biographical Highlights

Kurt Lewin was born in 1890 to a Jewish family in Mogilno, a small town in Prussia (presently Poland). His father owned a small store, and Kurt received an Orthodox Jewish education at home. He fought and was wounded in the First World War. He completed his doctoral degree in philosophy and psychology at Berlin University, where he also served as a professor from 1926 to 1932. During this period, he conducted experimental research in the following areas: needs, motivation, learning and tension states. Following Hitler's rise to power in 1933, Lewin and his family left Germany and emigrated to the United States, where he was employed on a research grant at Cornell University. While working there, he negotiated with the Hebrew University in Jerusalem regarding the establishment

of a research institute there. During that period, Lewin published two books in English: *A Dynamic Theory of Personality* and *Principles of Topological Psychology*. However, the move to the Hebrew University and the establishment of the research institute there never materialized. After teaching for 1 year at Harvard University, Lewin moved to the University of Iowa, where he headed a research institute on child welfare from 1935 to 1944. At the research institute, he conducted experiments on leadership styles and their impact on the performance of groups as well as on their social emotional atmosphere.

In addition to his academic and research activities, Lewin was involved in projects on organizational change. The term *action research* was first used in regard to a project implemented at the Harwood Manufacturing Corporation in Virginia. Eight years later, in two of his last papers, Lewin used the term in the context of a research methodology that aimed to improve inter-group relations and to reduce discrimination.

In 1945, Lewin moved to the Massachusetts Institute of Technology, where he founded the Research Center for Group Dynamics. The centre combined basic research on group processes and on attitude formation and change with efforts to solve social problems.

In his experimental and laboratory work, Lewin focused on the study of group atmosphere, as well as on leadership styles (autocratic, democratic and *laissez-faire*) and on the patterns of aggressive behaviour that developed in those settings. Later, he dealt with processes of decision-making and change in small groups. As for the topic of solving social problems, the Research Center for Group Dynamics at MIT conducted numerous action research projects. During one of these projects, which focused on training community leaders to work towards promoting better inter-group relations, the T-Group technology was developed. This technology later became the principal means of promoting change in organizational development.

Meta-Theory and Values

The term *field theory* indicates that the intellectual roots of Lewin's theoretical approach lie in both physics and psychology. According to field theory, behaviour needs to be evaluated in the right context, taking into account all the relevant forces that affect it. The psychological source of this theoretical perspective emanated from the Gestalt school.

According to the Gestalt school, every behaviour of individuals, groups or organizations is the result of the total situation in which it occurs. For Lewin, the total situation was the life space, or the field in which interdependent forces play a role. The life space has been defined as

the totality of fact which determines the behaviour (B) of an individual, group or organization at a certain moment. The life space (L) represents the totality of possible events. The life space includes the person (P) and the environment (E). Therefore, behaviour will amount to the following: $B = f(L) = (P \times E)$.

Lewin proposed six meta-theoretical principles that underlie field theory. Five of the six principles will be elaborated on here: (1) the psychological approach, (2) emphasis on the total situation, (3) the constructive versus the classificatory approach, (4) present time versus historical causation and (5) the dynamic approach.

The Psychological Approach. Lewin assumed that all psychological phenomena should be explained in psychological terms, even though he borrowed terms like *tension*, *vector* and *field* from physics. Consistent with the constructivist tradition, Lewin asserted that psychological phenomena are real. Therefore, the field that influences an individual should not be explained in the objective terms of physics. Rather, it should be explained in terms of the way it exists for that person at a given time.

Emphasis on the Total Situation. According to Lewin, researchers should always focus on the relationship between the specific group under investigation and its interaction with different internal and external forces. This leads researchers and agents of change to focus on the immediate situation in which the behaviour takes place.

The Constructive Versus the Classificatory Approach. The classificatory approach focuses on generalization from a specific object to an ideal one, which is an abstraction of the particular object. By contrast, the constructive approach stresses relational concepts.

Present Time Versus Historical Concepts of Causation. According to Lewin, derivation of behaviour from past experience to the present state is not valid. Rather, the past experience of a person or group counts only in terms of its manifestations in the present field.

The Dynamic Approach. According to Lewin, the behaviour of an individual or group is analyzed in the context of forces that enhance efforts to achieve goals when inhibiting forces obstruct those efforts. Reality is perceived as an ever-changing process of achieving equilibrium, which is continuously disrupted by the field of forces.

Democratic Values

Lewin was an admirer of the democratic system and its values. Many of his writings are imbued with his

deep conviction and high respect for democracy. He highlighted the merits and advantages of democracy in comparison with autocratic or laissez-faire regimes. He also believed that it takes generations for nations to learn the democratic way of living.

The components of action research are deeply rooted in the values of co-operation among researchers, practitioners and clients. These values are based on rational, transparent decision-making procedures and high regard for humanistic values. Lewin perceived democratic society as a pluralistic entity and insisted on granting freedom of expression and respect for the diversity of groups. He asserted that the parallel to democratic freedom for the individual is cultural pluralism for groups. However, he was sufficiently realistic to express his views about restricting freedom of expression for extreme groups in society. In that connection, he argued that a democratic society has the right to defend itself against destructive, intolerant cultures.

Theory of Change

Lewin referred to the topic of social change in his last article, 'Frontiers in Group Dynamics'. He described social change as a change of the force field and proposed that the change agent thinks in terms of how the present level is turned into the desired state. A planned change means that the equilibrium of the field force at level L_1 is replaced by a new equilibrium at the desired level, L_2 . Following the aforementioned meta-theoretical principle, the total social field of forces should be taken into account.

In this regard, changing people's attitudes or behaviour is tantamount to trying to break a well-established custom or social habit. Thus, Lewin termed social habits, which play a major part in preventing change, as *inner resistance to change*. In order to overcome inner resistance to change, it is necessary to apply an additional force which is sufficient to break the habit or to 'unfreeze' the custom.

Lewin defined the change process as consisting of three stages. The first stage is 'unfreezing' of the present level or habit. To achieve this, Lewin argued that it is necessary to break open the shell of complacency and self-righteousness. Thus, in order to change attitudes and behaviour, an individual needs to be stirred up emotionally. Gordon Allport referred to this process as catharsis. The second stage is 'moving', when the change actually occurs; and the third stage is 'refreezing', when the new habit or norm has been adopted and institutionalized.

Lewin believed that the best and most effective means of bringing about change in individuals is through group encounters. Hence, the group became

one of the major vehicles in action research and in organizational development.

Components of Action Research

Lewin did not succeed in systematically characterizing the components of action research before his untimely death. He had used the term *action research* as early as the beginning of the 1940s. In his last three papers, he offered a slightly more detailed definition of action research: 'The research needed for social practice . . . is a type of action research, comparative research on the conditions and effects of various forms of social action and research leading to social action'.

The following components of action research derive from Lewin's last three papers:

1. Action research is a planned problem-solving process that may extend over a period of time. It aims to examine and solve social and organizational issues. Lewin conceived of action research as a problem-solving process that occurs in a constantly changing environment. It consists of a spiral process of data collection aimed at determining intervention goals, followed by action aimed at implementing the goals and assessment of the results of the intervention. In principle, the intervention is continuous because problems that demand solutions arise all the time. In contrast to the normal scientific model, in which the researcher's main task is to investigate a problem or to test a hypothesis, the action researcher is expected to propose solutions to organizational and social issues. The first component of action research reflects several of Lewin's meta-theoretical principles. The action research paradigm deals with the interdependence between systematic examination of a social problem and efforts to solve the problem. This is an example of the Gestalt school perspective, which emphasizes life space and the need for researchers to take into account the concrete group or organizational situation. The spiral process of data collection that aims to determine goals followed by implementation and assessment of the goals reflects an additional meta-theoretical principle of field theory: the dynamic nature of the forces in the field where action research takes place. The action research paradigm also embodies the meta-theoretical principle of the constructive approach, namely, the need to construct a concrete unit of intervention (i.e. the idiographic, Galilean approach) rather than rely on a mechanical act of classifying the situation as a type of behaviour in accordance with a certain nomenclature.

2. Action research is a process in which the relationships between researchers and all other parties

involved in that process are managed in a democratic, co-operative and egalitarian mode. Among the parties involved, there is open communication and feedback regarding the effects of the intervention. Lewin's profound belief in and commitment to the principles of democracy are reflected in the action research paradigm. In this regard, he argued that believing in reason means believing in democracy, because the reasoning partners are granted a status of equality. According to the conventional scientific research model, the researcher directs the operation and is sometimes the only one familiar with the objectives or hypotheses of the study. In action research, by contrast, all parties involved in the process are responsible for the decisions that affect their lives. Equal partnership in the research project and knowledge of the context and rationale for the decisions that are made enable the parties involved to maintain high motivation and commitment. This component of action research also reflects Lewin's pluralistic perspective, which accords equal weight to the opinions and ideology of all parties involved in the action research project. Because each party has its own set of priorities and values, the only way for the action research project to succeed is to deal openly with the conflicts that arise. An ongoing process of managing and solving these power and value conflicts guarantees that the research will proceed as planned. This is in contrast to the conventional research design, where the principal investigator usually has the sole power to make decisions and solve conflicts unilaterally.

3. The small group serves as the principal means for achieving social change. Lewin perceived the small group as the most important vehicle for making democratic decisions and achieving change in people. He maintained that society consists of numerous and diverse groups and that the parallel to democratic freedom for the individual is cultural pluralism for groups. This speaks to the need to create harmonious inter-group relations in a heterogeneous, democratic society. However, the small group is also the cornerstone for reaching decisions in politics, in the family, in the community and in organizations. The dynamics created within the group make it possible for the individual to grow, to be socialized, to reach effective decisions and to plan the activities of the group.

4. Action research is a process that utilizes scientific knowledge drawn from the social and behavioural sciences and is carefully adapted to the context in which the intervention takes place. It creates and implements relevant methods of intervention and measures their effects.

Epilogue

Lewin's intellectual and theoretical legacy is as lively and relevant today as it was during his lifetime 70 years ago. A testimony to this is the intensive revival of research and theory regarding action research, as reflected in the present encyclopedia.

Apart from the important contribution of Lewin's field theory to action research and Action Science, Lewin's legacy to group dynamics and social and cognitive psychology is also vital. His theory regarding the phases of change in groups also relates to the concept of group atmosphere, which is now referred to as 'group culture'.

As for the relevance of Lewin's theories and constructs, it should be mentioned that he foresaw the gap between theory and practice in all the professions that the action research paradigm was applied to. Had he lived today, he probably would have reformulated his famous dictum from 'There is nothing as practical as a good theory' to 'Theory and practice should coexist in interdependent dialogical relationships'.

LGBT

LGBT is the acronym that stands for lesbian, gay, bisexual and transgender. It is an umbrella term used to refer to people whose affectation or romantic orientations differ from opposite sex attraction, or heterosexuality. LGBT people are called sexual minorities since they represent a subset of the general population. Estimates of the LGBT population are estimated to be between 4 and 10 per cent of the general population, and there is debate and even contestation over the precise numbers. However, it is accepted that LGBT people constitute a minority. *Lesbians* are women who are romantically or sexually attracted to women. *Gay* typically refers to men who are romantically or sexually attracted to men, although the term *gay* can also be used to characterize lesbians. In this case, the term *gay woman* has the same meaning as *lesbian*. *Bisexual*, which can represent males or females, means that the person is romantically or sexually attracted to people of both genders. *Transgender* is a term that represents people whose internal sense of gender does not match their biological sex. Transgender refers to males and females and includes those who cross-dress (i.e. wear the clothing of the opposite sex), those who adopt the affects or other demonstrable actions or accoutrements of the opposite sex and those who proactively elect to alter their physical sex through hormones and surgery. Gender identity represents the sense of maleness or femaleness that one experiences, and sex represents the biological maleness or femaleness. Sexual orientation refers to the romantic attraction that a person feels towards males or females. Sexual orientation can be heterosexual (opposite sex), homosexual (same sex) or asexual (the person is attracted to neither sex).

Stigmatization

LGBT people have experienced stigma because they transgress the generally accepted identities and practices of social activities such as dating and institutions such as marriage. LGBT people have historically experienced discrimination in covert and overt ways.

They have also experienced outright hatred and violence from those who believe that they are sinners, criminals or mentally ill. LGBT people have historically had challenges negotiating a variety of environments, including the workplace, the educational setting, health care, politics, religion and family of origin. Each one of these contexts—work, education, health care, religion and politics—represents an area in which action research—carried out for, with and by the LGBT population or subsets of the population—could offer insights and awareness around sexual minority issues. In the workplace, LGBT people have negotiated heterosexist environments in which sexual minority identity and sexual minority issues have been invisible and unaddressed. In educational settings, from K–12 to higher education, LGBT people have faced discrimination and marginalization that have ranged from covert discrimination to outright hostility and violence. In health care, there is a range of issues related to LGBT people. For example, gay men have experienced the devastation of the AIDS crisis that decimated their community during the 1980s. Lesbians have experienced challenges negotiating the health-care system, despite the fact that they are just as much at risk for certain types of diseases, such as breast cancer, ovarian cancer and cervical cancer, as the general female population. Bisexual people experience a unique kind of stigma, because they are often seen as ‘fence sitters’—that is, people who cannot make up their minds about their sexuality. As such, they face challenges related to stigmatization and marginalization not only among heterosexuals but also within the LGBT community itself. Transgender people face a constellation of challenges with respect to the workplace. When transgender persons decide to *transition*, which is a term that means that the person has decided to undergo the process of changing to his or her true sense of gender, they face the possibility of suffering discrimination, lack of support and understanding and may even risk losing their employment. The transition from one gender to the other involves a rather lengthy, complex and expensive process of hormone therapy, psychoanalysis and then surgery.

Identity Development, ‘The Closet’ and Coming Out

In addition to issues related to discrimination and marginalization, LGBT people face issues related to identity. There are models of identity development, notably Cass (1979), that offer suggestions about the process of realizing that one is gay, lesbian, bisexual or transgender. These models depict the stages of awareness, acknowledgement and acceptance of one’s sexual minority status that LGBT people experience.

Not all LGBT people experience these stages at the same time in their lives. For example, one person may realize at a very young age, even childhood, that he or she is an LGBT, whereas another person may come to this realization much later in life. In general, the integration of one’s identity with all parts of one’s life is associated with greater mental health. The term *closet* is used to refer to the act of concealing information about one’s sexual minority status. The phrase *coming out* signifies the act of disclosing such information.

Challenges and Opportunities Associated With Conducting Research on LGBT Issues

Research that raises awareness around issues related to LGBT people has the potential to help LGBT people experience greater freedom from societal stigma, and it also has the potential to help sensitize those who are not sexual minorities around these issues. For example, heterosexual persons would not second-guess the wisdom of placing a picture of their spouse and children in their workspace (e.g. cube or office space) and are not likely to feel uncomfortable answering questions about their family structure (e.g. husband or wife or children). The expectation, generally speaking, is that people are heterosexual. Those who are not face an ongoing series of challenges related to personal disclosure of their identity. Although it is worthwhile studying LGBT people as a population, it also bears noting that research is needed on each subset of this population because each subset has its own challenges and opportunities. For example, lesbians are homosexual females, and they face gender discrimination as well as sexual orientation discrimination. Gay men are homosexual males, and they face the challenge of having to negotiate expectations for masculinity. Bisexual people face the stigma related to being attracted to members of either sex, and they arguably are misunderstood and seen as particularly odd for their ostensible lack of commitment to a particular sexual orientation. Transgender people face challenges related to their gender expression, which does not align with their sex. They also face challenges if they determine that they want to transition. These challenges include negotiating the health-care system, the insurance system, the workplace, the family of origin and other family issues. For example, if a transgender person has a spouse, then the couple will have to make a decision about whether or not they will, during and after the transition, remain married to each other. There are other issues, such as child custody and child-rearing. These family-related issues can present themselves when gay, lesbian or bisexual persons come out after they have already established a

family life with an opposite-sex spouse and have children, but the issues are arguably more complex when someone transitions.

Issues related to conducting research with LGBT people also include confidentiality and access. Because the workplace laws that protect LGBT people from discrimination are uneven, nationally as well as internationally, LGBT people in the main continue to face challenges related to disclosure. Because of these challenges, action researchers committed to researching LGBT issues need to be sensitive to the safety and security—physical, mental, emotional and political—of their research participants. Because the closet continues to represent a very real way of life for LGBT people in a variety of contexts, identifying research participants can present a challenge for researchers, and asking them to self-identify and possibly even ‘out’ themselves in the process of co-initiating or co-facilitating an action research process is particularly contentious. Simultaneously, as with any subset of the population or any specific community or interest group, it is important that research is as self-led and self-determined as possible: hence the possibilities of action research for the empowerment and emancipation of often silenced or marginalized minority groups, such as this one. Action researchers, therefore, need to be sensitive to the potential pressures and unintended consequences which might arise from an invitation to participate or from an expectation of explicit engagement and open participation from fellow participants in the research process, and these expectations and any boundaries or safety mechanisms need to be carefully negotiated and protected. It is important when designing an action research project that the initiating researcher carefully attends to issues of the recruitment of research participants, the treatment of research participants and how they will protect the identities of their research participants. Granted, these are considerations for any researcher conducting research with any population. However, when LGBT people engage in an action research study, there is a possibility that they face a more complex set of considerations, particularly for those who are closeted.

LIBERATION PSYCHOLOGY

Liberation psychology is a framework that conceives oppressive social, economic, political and cultural conditions as root causes of psychological suffering. It focuses on understanding the manifestations and impact of hierarchical power relations of domination and subordination in psychological functioning. Unlike traditional psychology, liberation psychology explicitly presents a value system that guides the praxis. Liberation psychology addresses oppression, inequality and social issues through interventions aiming at collective social transformation. The assumption is that social issues such as warfare, poverty, class domination, racism, sexism, homophobia and others affect individuals and groups requiring individual and collective healing. In addition, it is necessary to change structures in order to eradicate the source of suffering and control over historically marginalized populations. Under this framework, people are conceived as active participants in their own process of liberation and healing by critically reflecting and collectively acting to change oppressive conditions. The role of the psychologist is conceived as accompanying and collaborating with the marginalized in their journey of liberation and transformation. This entry covers the background of

liberation psychology, its core ideas and its relationship with action research.

Background

Liberation psychology emerged from criticism of traditional psychology during the 1970s. Assumptions about universality and assertions of a values-free psychology were irrelevant for understanding the effects of oppressive power relations and unequal access to resources. Critics contended that valuing the individual over the collective, autonomy over interdependency, and individual change over societal transformation made the discipline complicit with the status quo, which aimed at defending the interests of a few at the expense of the majority.

In contrast, liberation psychology emphasizes a theory and practice concerned with social justice, equality and dignity. It has a preferential option for the oppressed majority as the subject of study; conceives an epistemology or nature of knowledge as grounded in history, social conditions, power relations and cultural norms and is a practice engaged in individual change and societal transformation. Its framework focuses on the understanding of people's situated experiences in their sociocultural and economic contexts. It also acknowledges that people's experiences of social issues vary, as well as their resistance to oppression. Consequently, liberation psychology attests that there are many psychologies rather than a single universal discipline. This is more appropriate for understanding how structures affect and connect people's varying experiences in different social relations. Examples include feminist liberation psychology, LGBT (lesbian, gay, bisexual and transgender) liberation psychology, Black liberation psychology and so on.

One of the major proponents of liberation psychology in Latin America was Ignacio Martín-Baró, a Jesuit priest, a social psychologist and an educator, who worked for the oppressed majority in El Salvador and was consequently assassinated there. Martín-Baró partially based the liberation psychology framework on Gustavo Gutiérrez's liberation theology, a preferential option for the poor, and on Paulo Freire's emancipatory education based on critical discernment. Martín-Baró thought that social justice must be the major concern of the social sciences. He contended that oppression impedes seeing reality. Under this premise, peoples' liberation is attained through a process of conscientization and transformation by critically decoding socially oppressive conditions and engaging in liberatory actions which bring hope for new possibilities.

He viewed the researchers' contribution as co-creating new research questions aimed at understanding as well as articulating solutions to social problems.

In so doing, the researcher is a contributor who exposes structural inequities and facilitates an awareness of distorted views of reality. Martín-Baró discussed the internalized view of fatalism of the rural population in El Salvador as an example of the psychological effects of a system of oppression which convinces people that their conditions are natural, normal and inevitable. The researcher then is of service to the people in their exploration of their reality and in co-defining a research agenda. Therefore, Martín-Baró proposed a methodology for generating knowledge based on a ground-up approach or critical realism in which the communities build theory from their everyday life experiences. This contrasts with the methodological idealism approach in traditional psychology, where the research project is defined by theoretical preconceptions of individuals' experiences.

Currently, Maritza Montero, a Venezuelan social psychologist, is considered a leading scholar in the field. The liberation psychology framework has also been applied in the USA, Europe and other parts of the world. An example is the feminist liberation psychology framework used to critically reflect on psychological theory that devalued and excluded the experiences and voices of women. Feminists coined the idea that the personal is political. In the field of psychology, this idea challenged notions that psychological patterns have their foundation at the level of the individual, ignoring the roots of psychological suffering residing in social conditions and differential power relations. The feminist view, like liberation psychology in Latin America, conceives liberation as a praxis of action-reflection towards personal, interpersonal and political transformations.

Liberation Psychology and Action Research

With an emphasis on empowerment, inclusiveness, diversity, equality of participation and solidarity, action research combined with a liberation psychology framework can promote a grounded process for democratizing knowledge. Action research provides a methodology for respecting, validating and listening to peoples' experiences and views; building theory through a ground-up collaborative process; bringing together knowledge and actions to redress inequities; documenting critical and liberating dialogues about power relations in each step of the research process and articulating findings that inform individuals, communities and policymakers to change oppressive social conditions. The framework of liberation psychology focuses the research on transformation at both individual and societal levels.

Action research addresses research challenges through an action-reflection praxis. A reoccurring

challenge is a tendency to separate research from action. The relation between these two areas implies that transformation requires not only understanding the roots of inequities at the personal, interpersonal and political levels but also articulating a plan of action to change them.

Action research fieldwork using a liberation psychology framework is a resource for communities to know and understand the world by discerning together about who they are, what their strengths and limitations are and what and how they want to change patterns of oppression and restore relationships, leading towards a more humane globalizing world.

LIBERATION THEOLOGY

Liberation theology is commonly understood as a form of theology that emerged in the 1960s and 1970s in response to changes in Catholic doctrine and ecclesiology. These changes combined with the determination of lay and ordained Christians from a wide range of ecumenical backgrounds to challenge structural oppression and economic disparities in the contexts in which they operated.

Though liberation theology is often thought to relate to Latin America, from where many of its chief exponents operate, it can also be seen to have emerged from the civil rights era in the USA and in various political liberation struggles in both Africa and Asia. Though it has emerged in predominantly Catholic nations, it is now a global and ecumenical movement comprising grass-roots efforts and organizations in both Protestant and Catholic communities.

Liberation Theology and Action Research

Its main contribution to the action research paradigm was the formation of the action/reflection model

(sometimes referred to in this context as the pastoral cycle) which encourages people of faith to constantly monitor their discipleship in terms of participation in activism and social involvement and, then, reflect on that activity with reference to scriptural understanding and the doctrine of the Church. That analysis should then inform the next stage of activism, ensuring that faithful thinking is rooted in praxis (acts) and vice versa.

Liberation theology is centred upon the notion that God wishes to liberate all those who suffer from oppression and that the biblical notion of the 'kingdom of Heaven', a place of peace, justice and fairness, is to be strived for as an active part of Christian discipleship. The theology is clearly influenced by the social sciences and is concerned with notions of power, social justice and equality. Among its many international exponents are Gustavo Gutiérrez (Peru), Leonardo Boff (Brazil), Juan Segundo (Uruguay), Elsa Tamez (Mexico), James Cone (USA), Elizabeth Schussler Fiorenza (Germany), Desmond Tutu (South Africa), Jon Sobrino (Spain), Naim Ateek (Palestine) and Ernesto Cardenal (Nicaragua).

Oppression of Liberation Theology

Liberation theologians have themselves often been victims of oppression due to their public 'prophetic resistance', and during the period of National Security States in Latin America during the 1970s and 1980s, many thousands were exiled, imprisoned or killed.

Some theological commentators predicted that the end of Soviet-style communism, heralded by the fall of the Berlin Wall in 1989 and the election of more conservative senior clergy in the Catholic Church at the end of the twentieth century, would signal the demise of this revolutionary form of theology. Liberation theologians, however, had little connection with East European Marxism and even less so with the decisions being made in Rome, so it continued to have an impact on theological development in Latin America, Africa and parts of Asia. In fact, the uncertainties in global capitalism following the financial crash in 2007 and the growing disparities between the rich and the poor in many nations have led to a resurgence of interest in the subject, even in the more affluent Western nations. Significantly, since the rise of Venezuela as a regional power in Latin America following the election of the Chavez administration in 1998, and the significant shift to the left throughout the region, many advocates of liberation theology have been elected into senior political posts throughout the continent.

The movement has influenced several significant political theorists such as the Brazilian educational

activist Paulo Freire and radical thinkers such as the Catholic priest Ivan Illich. It has also given rise to the development of 'contextual' theologies such as, among others, Hispanic, feminist, Black, disabled and queer theologies. The connection to these contextualized theologies can be understood by recognizing that for liberation theologians the starting point for faith is the concrete reality of the present time and that one's objective historical situation is an essential component in one's theological perspective. Liberation theology has also affected the development of practical theology, as people of faith are encouraged to examine the signs of the times and work out their responses to the political and historical positions they are immersed in.

The roots of liberation theology are often said to be in the developments of the Second Vatican Council from 1962 to 1965. This was initiated by Pope John XXIII and was continued after his death in 1963 by Pope Paul VI. It was widely interpreted as a period when the Catholic Church moved away from more traditionalist doctrines and attempted to modernize itself institutionally. Certainly, Vatican II gave permission for those who were advocating change in regard to the teaching and praxis of the Church to press ahead with reforms. Specifically, this resulted in the important influence of the Consejo Episcopal Latinoamericano (Latin American Episcopal Conference), also known as CELAM. This is a conference of the Roman Catholic bishops of Latin America, created in 1955. CELAM had pushed for the changes made during Vatican II and subsequently organized the 1968 Medellín Conference in Colombia, officially supporting 'base ecclesial communities' and the type of liberation theology later propounded by Gutiérrez in his 1972 essay 'A Theology of Liberation: History, Politics and Salvation'.

CELAM itself was a response to the growing radicalization of clergy and lay members following the success of the Cuban revolution in 1959 and a growing recognition of the horrific conditions of the poor throughout Latin America. CELAM's support of liberation theology was disliked by the Vatican, with Pope Paul VI trying to slow the movement after the 1962–5 Council.

With Alfonso López Trujillo's election in 1972 as general secretary of CELAM, conservatives regained control of the direction of the organization. Trujillo remained CELAM's general secretary until 1984.

However, at the 1979 CELAM Conference in Puebla, conservative elements within CELAM met with strong opposition from progressive elements of the clergy, who helped define the concept of a 'preferential option for the poor'. But with the election of Pope John Paul II, the conservatives took control of both the Roman Curia and the CELAM. Cardinal

Joseph Ratzinger (later Pope Benedict XVI) was charged with bringing back the Vatican's authority in the Third World. Under his guidance, in 1984 and 1986, the Catholic Church publicly condemned elements of liberation theology.

Wider international awareness of the liberation theological movement came to the fore with the execution of the El Salvadoran archbishop Oscar Romero in 1980. Following Romero's appointment in February 1977, progressive priests feared that his conservative reputation would negatively affect liberation theology's commitment to the poor.

Following the assassination of the progressive priest Fr Rutilio Grande in March 1977, Romero revealed a radicalism that had not been evident earlier. Throughout Latin America, Church hierarchies had often colluded with the state and the military to preserve the privileged position of the wealthy and the powerful. Romero, much to the annoyance of the Salvadorian elites, suddenly began to speak out against poverty, social injustice, assassinations and torture.

On 24 March 1980, one day after a sermon in which Romero had called on Salvadoran soldiers to obey God's higher order and stop carrying out the government's repression and violations of basic human rights, he was shot while celebrating Mass in a local hospital. Romero's story of resistance and persecution typifies the situations in which liberation theology was to develop throughout the 1980s.

Biblical Texts of Interest

Liberation theology is underpinned with the belief that the Bible gives a clear lead for the processes of liberation. Among its key texts of interest are the following:

- Exodus, which recounts the political and religious liberation of a group of oppressed slaves who, through the power of the covenant with God, become the people of God
- The Prophets, which gives a vigorous denunciation of injustices and argues for the rights of the poor alongside a proclamation of a new world to come
- The Gospels, which are full of dramatic pronouncements on the side of the poor and consist of numerous examples of Jesus' radical support for those who have been marginalized, disabled people, those in poverty, women, those of other faiths and sexual minorities
- The Acts of the Apostles, which demonstrates communitarianism and inclusive forms of community existing alongside the dominant idolatrous society

- Revelation, which offers symbolic language and resistance to the collective oppressions faced by God's people by the powers of this world

Themes of Liberation Theology

From these key texts emerge a number of themes important to liberation theology. The first concept is 'solidarity with the poor'. There is a common rejection of the ideas of charity and aid, primarily because those concepts can often be associated with the conservative notion of why people are poor in the first place. These concepts often regard the poor as objects of pity, which can exacerbate inequalities and power differentials between the oppressed and the oppressors. Liberation theology often rejects developmental or reformist responses to poverty, seeking instead approaches which challenge the fundamental problems at the root of social inequalities. Liberation theology demands solidarity alongside the poor, seeking solutions that are based on the struggles of those faced with real poverty and disadvantage. For this reason, it can often be a voice found alongside those calling for revolutionary changes within how the political, educational and cultural worlds operate.

Second, for liberation theologians, God is at work exposing and challenging the 'pharaohs' and 'powers that be' of any age. This leads liberation theologians to publicly condemn political, social and economic leadership which legitimates oppression. Liberation theologians therefore are often parts of movements calling for environmental, gender and economic justice.

Third, the project of the coming of the kingdom of God is an ongoing and ever-present reality. According to a liberation perspective, Christ's crucifixion and resurrection mean that victory over oppressive regimes and situations is assured. The religious journey, then, is to accompany the resurrected Christ in continually overcoming individual and structural sin, opposing actions which result in individuals or communities suffering from discrimination and persecution.

Fourth, the Church is a sign and an instrument of liberation. The Church needs to witness to a greater community of co-operation and love and needs to act to provide an alternative model of society based on equality and compassion. Gathered communities known as Base Ecclesial Communities, common in Latin America, are an essential component of this. These consist of groups of people who wrestle with the meaning of scripture and make it relevant to the struggles they face in their everyday lives.

For liberation theologians, the Church is a constant place of struggle. Church institutions can themselves often be instruments of oppressive structures,

harbouring sexist, racist, homophobic, disablist and other forms of discriminatory practice. However, the Church is also where God can be at work, and when the poor and the marginalized are able to 'evangelize the Church', there can be 'irruptions of the poor' within the ecclesial communities. When this happens, religious institutions can become instruments of liberation instead of oppression.

Conclusion

Liberation theology has come a long way from its initial stirrings in Latin America and the civil rights struggles of North America. The meeting of theologians in Petropolis, Brazil, in March 1964, in which Gutiérrez initially described theology as a 'critical reflection on praxis', has given rise to an enormous worldwide struggle to develop human and environmental rights. Since that time, many have been killed for espousing this theology of liberation; some have had the indignity of being silenced by their own Church institutions and forbidden to teach.

Despite all this, the influence of liberation theology is still evident in models of Church life and current forms of educational practice. Freire, a Brazilian educationalist who had a key influence on liberation theology, transformed models of teaching with his dialogical approach, which sought to challenge the way power was exercised in the learning process. South Africa may never have been released from apartheid in a predominantly non-violent manner had it not been for the work of liberationists such as the former archbishop Desmond Tutu. The Theatre of the Oppressed, developed in the 1960s by the Brazilian theatre practitioner Augusto Boal, has seen liberation theology having a significant effect on culture and the arts. Boal was influenced by the work of Freire, and his techniques use theatre as a means of promoting social and political change. In *The Theatre of the Oppressed* (1993), the audience become 'spect-actors', enabling them to explore, analyze and transform the reality in which they live.

Despite its critics, who accuse it of being too Marxist and too idealistic, liberation theology has shown itself to be an enduring phenomenon since its inception in the 1960s. It has proven itself to be an adaptable movement, responding to continual changes in the nature of oppressions and able to ally itself to indigenous and culturally specific liberation movements. From Dalit theology in India to Minjung theology in Korea and from Black, feminist, womanist and queer liberation movements to human rights struggles and peace organizations, liberation theology has clearly had a significant influence in the Modern Era. Its proponents converge with the action/research model by

seeking to use social scientific theory and methodology to continually adapt and inform the practice of both academics and activists.

LISTENING GUIDE

The Listening Guide is a feminist, voice-centred, relational and psychological methodology for narrative data analysis. Originally titled ‘The Reader’s Guide’, the Listening Guide was created by Carol Gilligan and a team of graduate students (including Diane Argyris, Lyn Mikel Brown, Elizabeth Debold, Judy Dorney, Barb Miller, Richard Osborne, Annie Rogers, Steve Sherblom, Mark Tappan and Janie Ward) in the 1980s at the Harvard University Graduate School of Education. This team of researchers developed the Reader’s Guide to render systematic the method Gilligan used in *In a Different Voice* and to address some significant shortcomings in psychological research methods at the time—that is, acknowledging the significance of the researcher’s subjectivity and the researcher-participant relationship.

The Listening Guide, as a feminist method, was originally designed to amplify voices that have been marginalized or silenced by dominant cultural frameworks. In the feminist methodological tradition, the Listening Guide intentionally acknowledges and attends to the positionalities of the researcher and the participant. Knowledge, as viewed by the Listening Guide, is relationally located in the participant’s relationship to self, culture and the researcher. It is represented by the

voices of the participant and given an opportunity to be heard in the relationship that evolves between the participant and the researcher. The Listening Guide invites psychological association and interdisciplinary knowledge—such as music and literature—into the research relationship and into the construction of new ideas. As such, this methodology is creative, unpredictable and generative.

This entry discusses the structure and process of the Listening Guide, the role of the interpretive community in the analytic process and educational action research applications.

The Structure of the Listening Guide

The Listening Guide is a polyphonic analytic methodology in that it seeks to pick up the many voices in which people speak of their lived experience. Its theory and practice are shaped by interdisciplinary theories stemming from the fields of psychology, literary analysis and music. In order to render such a complex understanding of a given narrative, the Listening Guide requires at least four separate listenings. The first listening, sometimes referred to as the ‘plot’ listening, asks the listener to construct a landscape of the interview. What stories are told? What are the major landmarks of the narrative (e.g. repeated phrases, words, contradictions, etc.)? What are the major themes? What are the silences, the stories left untold? In listening for the silences, the researcher becomes a ‘resisting’ listener, drawn from Judith Fetterley’s notion of the ‘resisting reader’. The first listening also requires a ‘listener’s response’ drawn from the notion of reader response theory. During this listening, the researcher attends to her own emotions, associations, reactions, questions and confusions. In this way, she can be sure to be alert to the issues that she brings to the analytic process and make every effort not to project her own voice onto that of the participant.

The second listening, sometimes referred to as the ‘listening for self’ is the core of this methodology. In this phase, the researcher is tuning in closely to the way the participants ‘speak of themselves’. The researcher must remain conscious of the fact that since it is a relational process, participants speak of themselves in relationship to the researcher in response to the questions asked and influenced by the place and time of the interview. In other words, this is a humble stance of listening for a self-in-relation. In order to hear the aspects of self that the participant shares in the interview, the researcher extracts ‘I phrases’ (the word ‘I’ plus the immediate following verb, e.g. ‘I want’, ‘I need’, ‘I think’, ‘I know’, ‘I don’t know’, etc.) in strict order as these phrases appear in the text. This ‘I’ is one representation of the participant’s self-in-relation, one

expression of how the participant expresses her lived experience. In extracting these phrases, Debold discovered that they fall in line poetically, forming what is often called the 'I poem', a way to listen for the ways the 'I' speaks. This 'I voice' is often in dialogue with other internal voices—sometimes a more removed 'you' voice, a collective 'we' voice or a distant 'she' or 'he' voice. When listening to the dialogue between these voices, the researcher can hear the internal dialogues that are often articulated as people reflect on the relational contexts of their lives. In describing the second listening, Gilligan often recounts that it is a way of magnifying the participants' voices or of making their voices more 'magnificent'. By drawing out the 'I voice', the researcher can temporarily quieten the surrounding voices, narratives and competing stories to hear the desires, confusions, questions and needs of the participants.

The third and fourth listenings, often referred to as the 'contrapuntal' listenings, help elicit the multiple voices spoken through the interview. The notion of voice here is distinguished from the notion of 'theme' in that voice is a more textured, nuanced and embodied articulation of a lived experience. In addition, the goal of this phase of the method is to hear the voices in relation to one another. Are they harmonic, dissonant, a marathon of solos or a clear duet? In listening for the tension between and among the voices, this set of listenings seeks to unearth the complexity of a narrative, rather than flattening it into a series of codes or themes.

The final step in the Listening Guide process is to create an analytic synthesis, bringing together the four listenings in an attempt to create an interpretive narrative. The standard for validity in this process answers the question that Gilligan often poses in relation to this step in the Listening Guide analysis: 'If I followed your footsteps, saw what you saw and heard what you heard, would I understand how you reached this interpretation?' Once an analytic synthesis is rendered, the researcher returns to the participant to explicitly inquire how the participant views the synthesis and to surface areas of interpretive agreement and disagreement.

The Role of the Interpretive Community

The Listening Guide requires that the researcher construct or join an interpretive community in which his emerging interpretations can be articulated, confirmed and challenged. The centrality of the interpretive community, clearly described by Stanley Fish in 1980 and later by Mark Tappan in relation to the Listening Guide, stems from the importance of helping the researcher to see his blind spots that may be hidden because of his own cultural, relational, professional and/or personal experiences. In one particularly vivid example, Jill

Taylor, Carol Gilligan and Amy Sullivan describe the centrality of the interpretive community in their use of the Listening Guide in order to understand girls' experience of race and relationship. In their study, they discovered that in order to hear the nuances, silences, resistances and hints in discussions of race and relationship, they needed to continually expand and grow their interpretive community to include women of different ethnicities, races and socio-economic classes. They found that this evolving community became so central to the work that they created retreats for the researchers to process their own experiences of race and relationship.

The interpretive community is also a key aspect of the validity/trustworthiness process of the Listening Guide. It can help the researcher construct, challenge and evaluate the trail of evidence that supports a given interpretation. Within this forum, interpretations can also be corroborated, deconstructed or augmented by co-researchers.

Applications of the Listening Guide

The Listening Guide has been used in many educational action research and action-oriented studies. Originally designed for studies of self and moral voices, it was used to listen for voices of resistance and capitulation in the Harvard Project on Women's Psychology and Girls' Development's (Harvard University Graduate School of Education) landmark study of girls' development at the Laurel School (Cleveland, Ohio) in the mid-1980s. The results, reported by Brown and Gilligan in *Meeting at the Crossroads: Women's Psychology and Girls' Development* (1992), were deeply influential in understanding the experiences of both students and faculty at the school and, more generally, in thinking about girls' education. Similarly, Gilligan's study at the Emma Willard School in Troy, New York, led to changes in practice at the school and the collaborative publication of the volume *Making Connections: The Relational Worlds of Adolescent Girls at Emma Willard School*.

While the Listening Guide was originally used in psychological research, it has since been used to understand relational experiences in the fields of education, history and women's studies. Raider-Roth has used the methodology to examine how children and teachers understand the ways their relationships with one another shape student learning and teacher practice. In an effort to understand the relational world of boys in school, at home and in their friendship worlds, Niobe Way and Judy Chu utilized the Listening Guide to hear the multiple voices and tensions expressed by the boys they interviewed. Similarly, the Listening Guide has been a core methodology in Lyn Mikel Brown's work

in understanding the relational worlds of working-class girls. Internationally, Tova Hartman has applied the Listening Guide in listening closely to the voices of modern women in orthodox religions, while Natasha Mauthner in the UK and Andrea Doucet in Canada have theorized the ways in which the Listening Guide offers a unique stance for accessing the methodological, epistemological and ontological subjectivities of the researcher and participant. Numerous doctoral students have used the Listening Guide as a core methodology in their action research dissertations, such as Eric Gidseg's investigation of teachers' relationships with the self and others in the face of the US Federal education policies; Christina Cruz' research on female coaches' relationships to the self, others and their profession in university athletics; Vicki Stieha's study of teachers' understandings of the relational web of school life; Billy Hensley's examination of LGBTQ (lesbian, gay, bisexual, transgender, queer or questioning) university students' understanding of the notion of 'safety' on their college campuses and Angie Woods' study of college students' relationships to language, culture and community when engaging in service learning courses, among many others.

While the Listening Guide's application to the field of educational action research is relatively recent, it offers a unique opportunity to understand the psychological and relational dimensions of educational experiences. Such understandings can help practitioners and researchers shape educational experiences to be more relationally aware, in tune and caring, thereby fostering healthy resistance and resilience. In such a climate, genuine and robust knowledge grows and flourishes.

LIVING LIFE AS INQUIRY

Action inquiry is the process of bringing a fierce curiosity to every aspect of one's life. It is an ongoing process of questioning one's experience, paying attention to what one finds and making appropriate adjustments as one goes along. For an action inquirer, every moment of every day can become a subject of curiosity and investigation, every part of life grist to the inquiry mill. 'Living life as inquiry', a phrase coined by Judi Marshall, captures this pervasive nature beautifully. Individuals' beliefs, values, aspirations, feelings and behaviours are all interconnected aspects of their experience, and action research involves opening all of that up for questioning and dealing with what is discovered through thoughtful processing and appropriate action. It involves being curious as to whether and how what one actually does is congruent with what one espouses and engaging with any discrepancies between one's values and one's actions. Living life as inquiry means paying attention to the stories individuals tell themselves about their world and about themselves within it and being mindful that they are all constructions, influenced by their perspective and by their purpose. Social constructionist paradigms point out that the social context shapes discourse and influences the values held and that any descriptions given of the world, or any account given of personal experience, are culturally situated and subjective. Action researchers need to work with the challenging implication that their view is not the truth and that others may have very different versions of reality.

Inner and Outer Arcs of Attention

Action inquiry involves what Marshall calls 'inner and outer arcs of attention'. Inner arcs refer to developing self-awareness, noticing meaning-making processes, patterns, themes and repetitions, while in the midst of action. This can be hard work, because this discipline is not part of any personal, organizational or scientific

culture. What one notices and how one makes sense of it will be edited by consciously and unconsciously held purpose and assumptions, which in turn will be coloured by one's age, class, gender and so on. Unresolved distress from earlier experiences may well distort one's perception of the situation and the way one conducts oneself in it. Reaching out to others can help individuals avoid becoming solipsistic and caught up in their unaware projections. Marshall calls this process of engaging with others in testing our own sense making and perceptions 'outer arcs of attention'. On occasions, individuals may engage with others to inquire collaboratively into a topic of common interest; sometimes they may seek affirmation of their meaning making; at other times, they may purposefully engage with differences of views and perspectives. Note taking and journaling and reviewing one's notes for emerging themes, regarding both inner and outer attention, are an important part of this self-reflective process. Some researchers develop other strategies to track their reflections, using voice recordings, imagery or other channels that suit their reflective process better. This highlights another important characteristic of life as a process of inquiry: the multiplicity of ways of knowing.

Multiple Ways of Knowing

Self-reflective inquiry processes require researchers to pay attention to the different ways in which we engage and come to know our life world. Intellectual, thought-based sense making is rather privileged in Western cultures, but it is only one of the myriad of ways in which humans develop a sense of their world. Propositional statements and intellectual knowing cannot do justice to the richness and challenges of the human condition. Action research argues for a multidimensional account of knowledge and research outcomes. Feelings, sensory information, intuition and imagery are all sources of knowing, as is the practical knowing of how to do something. Rigorous inquiry requires researchers to attend to and engage with those different ways of knowing and their interconnection.

Cycles of Action and Reflection

The classic action research process is often described as 'a plan, act, reflect' sequence: I may prepare for an engagement, planning how I want to proceed, paying attention as I am immersed in the encounter, reflecting in the moment and afterwards on my experience and then planning some more for the next encounter, based on the results of my effort.

The cycle of action and reflection is rarely this neat, and many action researchers have written about

the somewhat unexpected tendency of their inquiry to develop a life of its own. What the researcher had assumed was figural becomes peripheral, and what was not even on the radar yesterday has become utterly figural today. Nor does the notion of 'cycles' do justice to many researchers' sense of a developing depth in their inquiries. Hence, they talk of experiencing their research as evolving in a spiral, an image that also allows for the sense of sometimes honing in, going deeper, and at other times zooming out, coming up for perspective. Whatever the image, this movement back and forth between action and reflection tends to generate its own momentum, often triggering different forms of attention and sparking further experimentation. The process of tracking this movement is a key aspect of living life as inquiry.

Connecting Theory and Practice

Whilst action researchers may have a different emphasis or way of framing their work, there is broad agreement about an overarching purpose centring on the flourishing of life, human persons, communities and the wider ecologies of which we are part. Action researchers are not alone in these aspirations. One important outer arc of attention consists of reaching out to those fellow travellers and engaging with their inquiries. For the longest of times, published writing—books, articles in academic and practitioner journals—was the main avenue to share knowledge. Increasingly, there are other, web-based avenues available for that purpose. It behoves researchers to engage with others' contribution to knowledge as a source of challenge or support to their thinking and their practice. At the same time, they can make their own contribution by critically questioning others' thinking from the ground of their own practice. Thus, in an iterative process, they weave practical and theoretical strands as they deepen their understanding and develop their practice.

When they do this cycling, deepening and interweaving well, the process becomes more of an attitude, a way of life, than a contained process: hence the aptness of the term *living life as inquiry*. The following incident in the life of an action researcher illustrates these qualities of curiosity, inquiry and reflexivity as they are embodied and manifested in even seemingly mundane aspects of daily practice:

I decide to take a taxi to my client meeting. The initial pleasure of avoiding a packed underground train quickly dissipates as the driver becomes increasingly irate with the heavy traffic and, at the top of her voice, starts a running commentary on other drivers, cyclists, traffic lights and the state of the world. I had hoped for some quiet thinking time, and I only just manage to contain my irritation. I pay attention to my inner

dialogue and realize with some embarrassment that I am in the process of forming some fast judgements of this young driver (e.g. impatient, inexperienced, lacking in social skills). As I interrupt my stream of thoughts, I become curious about this person, her distress, her choice of job and her circumstances. Rather than sit in silent but brooding judgement, I strike up a conversation with her. No, she really doesn't like her work, she doesn't actually like driving and she hates rush hour traffic, but it's her only way to provide for her two children and work around their school hours. Once they're big enough, she'll go back to university; she wants to study international business, so she's learning French at night. It's tough. Thoroughly cured of my prejudgements, I am glad I asked, and when I get out of the taxi, she smiles when she says, 'Have a nice day'.

Light and Dark

However much discipline it may require, living life as inquiry need not be a chore. It can be compelling and joyful. Being curious about mundane, scary or downright boring activities can bring a playful quality to them that can make them fun and interesting. And yet it is important to acknowledge the potential shadow sides of seeking to live life as an ongoing inquiry process. It can be quite unsettling. The introspection it involves can swamp individuals, and they can become too self-absorbed, unable simultaneously to move outwards. Moreover, recognizing multiple perspectives and engaging in framing and reframing can leave them discombobulated, as their taken-for-granted frames, which used to anchor them, no longer provide a safe hold. As one person, 3 months into an action research endeavour, put it, 'I find myself utterly disconcerted about the fact that everything I have taken for granted about my practice for all those years, now seems to be up for grabs'.

Living life as inquiry is rewarding and demanding, enlightening and unsettling and utterly worthwhile. As Socrates said, 'The unexamined life is not worth living'.

LIVING THEORIES

Living theories is a term coined by the educational action researcher Jack Whitehead to describe contributions to action research emerging from enquiries of the kind 'How do I improve what I am doing?' in the context of a professional working life in education, most particularly between 1967 and 2012. Perhaps the most significant contribution is in the original idea that individual action researchers can create their own living educational theories as explanations for their educational influences in their own learning, in the learning of others and in the learning of the social formations in which they live and work.

The idea of living educational theory was developed from a question asked by the logician Edward Ilyenkov: If an object exists as a living contradiction, what must the thought (statement about the object) be that expresses it? This question emerged from a 2,500-year-old battle between propositional and dialectical thinkers. Using Aristotelean logic, propositional thinkers eliminate contradictions between statements in 'correct thought', through a process that conceals as much, or indeed more, than it reveals. This entry focuses on the origins and development of a living theories approach to educational action research, originating in the work of Whitehead and colleagues at the University of Bath but spreading far and wide in more recent times. The reach and influence of living theories in various contexts worldwide is exemplified.

The recognition of existing as a living contradiction came to Whitehead in 1972, on viewing videotapes of his own classroom practice at a comprehensive school in London. While he believed that he had established

inquiry-based learning with his students, in which he responded to the questions they asked, the videotapes actually showed that he was giving students the questions rather than enabling them to formulate their own. This was an embarrassing revelation and an example of the power and value of visual data on one's own practice to reveal one's existence as a living contradiction.

Further perceived contradictions within the field of educational theory contributed to the development of the living theories approaches to action research. In particular, the validity of the disciplines approach to educational theory, which holds that educational theory is constituted by the philosophy, psychology, sociology and history of education, is questionable. A number of educational theorists, including Paul Hirst, one of the proponents of the disciplines approach, along with Richard Peters and other philosophers of education, acknowledged that the weakness of the disciplines approach was its focus on the replacement and displacement of the practical principles which teacher-practitioners could use in explaining their educational influence on their own learning and on the learning of their pupils. Hirst acknowledged this error when he wrote that such practical principles were regarded in the disciplines approach as at best pragmatic maxims, representing an initial crude and superficial justification in practice that in any rationally developed theory would be replaced by principles with more fundamental, theoretical justification. Having articulated this weakness, he sought to rectify it with the suggestion that rationally defensible principles must in essence stand up to such practical tests and are necessarily inadequate without this.

The living theories approach to educational action research emerged from endeavours to rectify the weaknesses and blind spots of the disciplines approach and to contribute to the creation of a valid approach to educational theory. Whitehead's involvement in the mid-1970s in an early school council local curriculum development project led to the production of two evaluation reports. The first explained the project in terms of contemporary models of changes in teaching and learning and models of curriculum innovation and was praised by academic colleagues. However, the teachers involved criticized the report on the grounds that they could not see themselves in it. Returning to the data provided by videotaped conversations with pupils and teachers, they reconstructed the report into a form that the teachers agreed was a valid explanation of the project. This had the form of expressing concerns and problems; imagining ways forward; acting on a chosen action plan and gathering data on which to make a judgement on the effectiveness of the actions; evaluating the effectiveness of the actions; modifying the concerns, plans and actions in the light of the evaluations

and producing a validated explanation of the teachers' and researchers' own learning as they worked collaboratively to help the pupils improve their learning.

This experience culminated in a refined, explicit understanding of (a) the place of action-reflection cycles in improving one's practice and (b) the role of the individual, the inclusion of 'I', as a living contradiction, as one whose enacted values and actual behaviours are not always in line with those one espoused. From this, Whitehead originated the idea of individuals capable of generating their own educational theory as an explanation of their educational influence in their own learning, in the learning of others and in the learning of social formations.

The focus thereafter was on supporting practitioner-researchers to generate their own living educational theories, most notably through their engagement in postgraduate study. The fruits of these endeavours are evident in a significant number of M.Ed., M.Phil. and Ph.D. degrees awarded by the University of Bath in the period from the mid-1980s onwards, in which practitioner-researchers sought to develop and embody their own living theories. Between 1996 and 2012, some 32 living theory doctoral theses were successfully completed, and these can be accessed from the living theory section of <http://www.actionresearch.net>.

The most significant transformation in the nature of the living theories produced between 1996 and 2012 has been in the use of multimedia narratives with digital video. Until 2004, the regulations of the University of Bath for the submission of research degrees did not explicitly permit the submission of e-media. The regulations were changed in 2004 to permit such submissions, and Mary Hartog's thesis (see above web link) was the first to be submitted with e-media. This change of regulation permitting the submission of e-media occurred at the same time as an extension and transformation in epistemologies for the educational action researchers involved in postgraduate supervision and study at the University of Bath's Centre for Action Research in Professional Practice. This epistemological extension and transformation involved—through the influence of Alan Rayner, a colleague at the University of Bath—a relationally dynamic awareness of space and boundaries within explanations of educational influence. Whilst insights from propositional and dialectical researchers continue to be valued, a living theories approach increasingly encourages the creation of living educational theories that are informed by an inclusional awareness of space and boundaries. Videoclips that show oneself in an educational space with others are particularly valuable in developing such a dynamic awareness. The awareness of natural inclusionality does not deny the existence of oneself as a living contradiction, nor does it deny the value of

insights from propositional theories. Instead, it overcomes some of the limitations in propositional and dialectical theories, especially in so far as it communicates the embodied expressions of energy-flowing values within educational influences in learning.

The growing influence of the living theories produced by action researchers can be seen in many different contexts throughout the world. In China, with the support of Dean Tian Fenjun and Professor Moira Laidlaw, the Chinese government agreed to the establishment of the Experimental Centre for Educational Action Research in Foreign Languages Teaching at Ningxia Teachers' University. In Japan, Je Kan Adler-Collins successfully completed his doctoral inquiry into bringing a curriculum for the healing nurse into a Japanese University through action research and living theory. In Canada, Dr Jacqueline Delong is continuing with her postdoctoral enquiries and in supervising action research dissertations whilst responding to moves to support scholarly enquiries beyond written text in journals such as *Teacher and Teacher Education*. In South Africa, the Transformative Educational Studies project, funded from 2011 to 2014 by the National Research Foundation of South Africa, has the overarching research question 'How do I transform my educational practice?' A number of living theories of South African educational action researchers have been successfully completed as dissertations for higher degrees, and some have been published under the guidance of Professor Lesley Wood.

In terms of the contributions of living theories to transforming understandings of educational knowledge and theory, the first issue of the multimedia journal *Educational Journal of Living Theories* was published in 2008. This journal is dedicated to the publication of living educational theories with action research. The 2011 special issue 'Digital Creativity and Video in the Workplace', edited by Yvonne Crotty, highlights the advances made in the use of multimedia narratives in the creation and publication of living educational theories with action research at Dublin City University in Ireland. The Collaborative Action Research Network Study Day in the Centre of e-Innovation, Pedagogy and Workplace Learning at Dublin City University, in October 2012, focused on 'Multimedia Forms of Representation in Living Educational Theories in Relation to Improving Practice'.

At the time of writing this entry, the latest living theory doctorates with action research to be successfully completed are those of Marie Huxtable, Yvonne Crotty, Keith Kinsella and Mark Potts. At the heart of a living educational theory is individuals' responsibility for accounting for their influence in terms of the values they believe carry hope for the future of humanity. Potts has analyzed his learning in the exercise of his responsibility in terms of the value of living citizenship

within educational contexts in schools in the UK and in South Africa. Huxtable has accounted for her learning in living as fully as possible her values of loving recognition, respectful connectedness, educational responsibility, inclusion, emancipation and equality. Kinsella has accounted for his learning in presencing developmental opportunities for his students and in presencing empathetic responsiveness in relation to their learning. Crotty has brought an educationally entrepreneurial spirit into the academy as a living standard of judgement. Her explanation includes a responsibility for students and her values of passion, care, safety, creativity and excellence within her practice.

By accepting responsibility for accounting for their own lives and learning in enquiries of the kind 'How do I improve what I am doing?', living theory action researchers continue to make original contributions to knowledge whilst providing evidence that they are fulfilling both halves of the mission of the American Educational Research Association. This mission is to advance knowledge about education and to encourage scholarly inquiry related to education and, simultaneously, to improve practice and serve the public good.

Each of these living theories is unique in the sense that the contributions to knowledge are formed from the unique constellation of values and understandings that have emerged from each autobiography in enquiries of the kind 'How do I improve what I am doing?' Their relatability, rather than generalizability, can be seen in the evidence that the living theories of action researchers are inspiring others around the world to create and share their own living theories, in a pooling of the life-affirming energy with values that carry hope for the future of humanity.

LOCAL SELF-GOVERNANCE

The literal meaning of self-governance is governing oneself rather than being governed by others. Local self-governance thus connotes a process of collective discussions, collaborative learning and collaborative actions by the local community and its leadership on the basis of their collective knowledge. Here, citizens are not just subjects but also the actors and the decision-makers. The process of local self-governance includes interesting examples of action research approaches and methods.

Historically, many communities and societies have had experiences of practicing self-governance. Ancient literatures from India, China, Japan, Australia, northern America and Europe mention different forms of local self-governments. From Plato to Gandhi, many philosophers have eloquently explained the concepts in governance and local self-governance at different periods of time in history. Historical Indian literatures mention that local self-governments were popular in different republics in India around 600 BC. Gandhi, in fact, saw self-government of the village community, called the *panchayat*, as the basis of Indian democracy. Barangays in Philippines and communes in Italy are two examples of modern forms of local self-governments.

Local Self-Governance and Action Research

The case of local self-governments in India demonstrates how the principles and practices of action research are applied to local self-governance. The term *Panchayati Raj*, local self-government in rural India, refers to a system of governance which includes a *gram sabha*, an elected panchayat and support officials. A *gram sabha*, or a village council, is a permanent constitutional body comprising all the adult residents of a village. All members of the *gram sabha* have equal opportunities and rights to interact, identify and discuss the problems and together find out solutions. The *gram sabha* promotes collaborations and co-operation among actors for inquiry, knowledge and action. The *gram sabha* elects the body called the village panchayat, which is the elected executive. Village panchayats (or simply panchayats) are constitutional local governments mandated to work for economic development and social justice in their villages. In doing so, the elected panchayat seeks guidance and support from the *gram sabha* in identification and prioritization of problems, mapping of possible resources and planning for future collaborative actions to achieve agreed solutions for the collaboratively prioritized problems in economic and social development of the village. The whole process provides a good example of an action research process or interactive inquiry process that balances problem-solving actions implemented in a collaborative context with data-driven collaborative analysis of underlying causes and realistically possible solutions.

While the concept of local self-government is as old as the history of humanity, it did evolve slowly till very recently. As most countries experiment with democratization and decentralization in terms of planning, decision-making and public service delivery, new forms of local self-governments are emerging across the world. But despite varying forms and mandates, local self-governments more or less promote the practices of action research in their governance and development approaches.

Differences Between Local Self-Governance and a Democratically Decentralized Government

Local self-government in modern literatures is sometimes treated as synonymous with the *democratically decentralized* government, but the two are in fact different, though related, concepts. Since the type of governance is closely associated with a form of government in all political literatures, local self-governance is often identified with the structures and systems of government at the local level. The very notion of

local self-governance, many thinkers and practitioners believe, logically accepts the existence of government at non-local (central or provincial) levels. So the existence of modern local self-government is in relation to its counterpart at the central and province levels: the central government and provincial governments.

Decentralization of government may lead to the formation of local government, but the governance there may not necessarily be self-governance. However, *democratic decentralization* of government provides greater opportunities for self-governance. So the word *self* in the term *local self-governance* seems to be emphasizing the democratic form of decentralized governance. Thus, the concept of democracy is integrated with the concept of local self-governance in current contexts. So, wherever used, the word *decentralization* often refers to democratic decentralization—not any other form of decentralization.

It is interesting to note that two polar concepts—globalization and democratic decentralization—are being experienced and experimented with in the world at the same time. While globalization connotes a sort of centralized global order, democratic decentralization in many countries connotes the establishment and practice of local self-governance. Many African, Asia-Pacific, American and European countries initiated the process of decentralization to provide their citizens ample opportunities to participate in the governance process at the local level by establishing legal local governments. Accordingly, different countries introduced legal structures and systems of local governments by legislatively incorporating the local self-government acts. European Charter of Local Self Government, for example, was adopted in 1985 by Congress of Council of Europe. The charter asked all member states to guarantee political, administrative and financial independence to their local self-governments on the basis of the principle of subsidiarity. Similarly, Local Self-Governance (or Government) Acts have been enacted in many countries across the continents since the early nineties. These acts or orders help evolve and strengthen decentralized governance at the local level.

Many authors have typified local governments in different types on the basis of the relatively recent experiences of different countries in decentralization.

As the terms *local self-governance* and *decentralization* have become almost synonymous in modern political practices, it is important to understand the concept of decentralization. Though different countries have different experiences in decentralization, decentralization across the world quite often refers to the transfer of powers from a central government to lower levels in a political-administrative and territorial hierarchy.

Local self-governments in most countries are an outcome of democratic decentralization. The levels of politico-administrative decentralization of powers and authorities from their central governments to these local governments differ from country to country. One can accordingly observe varying strands, methods and processes of action research in different local self-governments.

M

MĀORI EPISTEMOLOGY

The people of Aotearoa/New Zealand live in a group of islands located in the remote South-West Pacific. The indigenous Māori migrated from Polynesia and settled there about 1000 AD. European contact began in 1642, with a rapid increase in migration in the early years of the nineteenth century. In 1840, a treaty, *Te Tiriti o Waitangi* (The Treaty of Waitangi), was signed between Māori and the British government, establishing Aotearoa/New Zealand as a British colony. It is now an independent country with a democratic government and a capitalist economy. Māori constitute a substantial minority population, while *Pākehā* (the term now used for descendants of European migrants) are the majority. There are also other migrant groups, including substantial numbers from the Pacific islands, Asia and India. English and Māori are the principal languages of the country, with English being the lingua franca. The treaty guaranteed certain rights to Māori but, despite this, Māori suffered grievously from the process and impact of colonization. Adversities included disease, warfare, alienation, confiscation of their land, loss of their language and disruption of their culture. Among the many legacies of this today are relative poverty, educational underachievement and physical and mental health problems. From the middle of the nineteenth century to the middle of the twentieth century, the treaty was extensively dishonoured, but since 1975, legislation has increasingly enshrined the treaty in modern national law, established a tribunal to adjudicate on claims by Māori against the government for treaty breaches and marked the ushering in of a 'bicultural' perspective that now infuses all national life, although to varying degrees depending on place and context. Although still argued about, two central principles of this bicultural perspective are those of 'partnership' (between the government and Māori) and *rangatiratanga* ('authority over one's own

things', 'self-determination'). It is from this sense of there being two equal treaty partners that the 'bi' in 'bicultural' comes. Arguably, the treaty has enabled two cultures—Māori and Pākehā—with distinctive histories the opportunity to embrace mutual understanding and power sharing and to provide a functional framework for culturally inclusive epistemologies.

Traditional Māori society, not unlike other indigenous societies, values high-level thinking and analytical skills, exemplified in compellingly clear understandings of cosmology, geography and technology. For Māori and other indigenous groups, these skills might be exemplified in quite different ways. For example, the Māori practice of producing resources made from flax requires a precise knowledge of the physical properties of raw materials, their source, the details regarding *tikanga* ('customary practices') surrounding the collection and processing, their sustainability and so on.

A second example shows that as a result of successive generations of purposeful voyaging across the oceans, an extensive knowledge of navigation was accurately acquired. Such knowledge was acquired through active participation within culturally responsive and authentic learning contexts. As is the case with other indigenous groups, Māori had to systematically research, trial and experiment with the qualities, properties and habits of birds, plants and other natural resources. Their scientific endeavours were recorded and transmitted through song, symbol, story, dance and everyday practices.

It is clear, however, that the scientific endeavours and knowledge of Māori and other indigenous people, as well as their ways of transmitting this knowledge, are seldom evidenced in the curriculum and the pedagogical practices imposed on them from 'outside' systems. These anomalies continue to be perpetuated in education by way of successive policies of assimilation, integration, multiculturalism and biculturalism. During the past 25 years, however, there has been

considerable indigenization of the sector, whereby cultural epistemology is a salient rather than an obscure phenomenon. There has been a revitalization of the Māori language, indigenous schools are on the rise and greater numbers of Māori scholars are completing doctoral qualifications in either mainstream or indigenous universities. What began as a cathartic and liberating epistemological revolution might now be described as an embedded and rightful entitlement. Māori epistemology is ubiquitous. The impact on the field of action research is growing, led by indigenous scholars in places like Aotearoa/New Zealand.

Action Research Based Upon Māori Epistemology

Given the assertions that indigenous groups have always had their own distinctive epistemologies, and that these were often given minimal credence by the dominant group, there is an argument that it would seem to reposition the emphases. If alienation from the land and the language negatively affects one's cultural identity, then there has to be a constructive repositioning to attain proximity to the land and the language. If the struggle to retain identity while battling to participate in the wider society presents challenges, then the repositioning has to be around reclaiming a strong identity and enabling a voice in the wider society.

A recent (2012–14) action research study in Aotearoa/New Zealand is looking to enhance the ways education communities respond to issues of inequity. The study seeks to describe indicators of the educational success of young Māori students identified as high achievers by their peers, teachers and family members. There are strong tribal affiliations in terms of geographical location and by virtue of the fact that participants and researchers are all from the tribe under study. The research activities have been validated by tribal leaders as well as a conventional university. Eight indicators of success form the basis of the investigation: identity, diligence, relationships, creativity, well-being, scholarship, humility and values. *Identity* is about knowing one's world and language. *Diligence* is about the ability to focus on and complete tasks. *Relationship* factors determine the kind of interactions that make for camaraderie at all levels of the community. *Creativity* draws from the deeds of past heroes who were prepared to 'have a go' at things. *Well-being* considers the focus on a healthy body, mind and spirit. *Scholarship* looks at an emphasis on valuing education in all its forms—traditional and contemporary. *Humility* measures an appreciation of service to others and putting the needs of others ahead of the self, as well as ways to deal with criticism. *Values* refer to the core ideals from indigenous cultures based on a kinship

with nature, caring and spirituality. The lenses through which these eight qualities are defined are located from within indigenous epistemologies.

A Braided River Discourse

One of the advantages that the concept of discourse affords is a view of the relationship between competing discourses. While there are a range of discourses specific to knowledge and epistemology, they are seldom competing on a level playing field. Conventional discourse refers to those epistemological ideas that are perceived to have a privileged or superior orientation. Indigenous discourse refutes this stance. It is timely to consider a braided river discourse (or framework), where a convergence of both streams of epistemology is likely to be more powerful than either one on its own.

In an effort to explore both the structural and the symbolic forces at work in culturally inclusive action research, it is important to acknowledge the relationship between scientific and indigenous typologies. The braided river framework proposes that culture is materially, socially and ideologically constructed and embedded in the lives we live. It is not a stand-alone framework that can simply be applied regardless of context. It is a framework that is cognisant of particular trials and tribulations, is insistent on the specificity of the community ties, is mindful of the availability or lack thereof of resources and is intent on wishing to enable rather than subvert the potential of a blending of streams of consciousness in the planning and design of action research.

MAP-MAKING

Map-making is a voluntary representation, from Latin *re-* ('again') and *praesens* ('make present', 'visible', 'understandable'), aimed at bringing to attention again 'things' that are past and/or far away. Compared with other forms of representation, map-making aims at representing how things are related to each other within a certain 'space' that can be abstract (conceptual maps, mathematical maps, etc.) or can refer to physical reality. The most common type of map is the geographical one: a *graphic* representation, at various scales, of a certain portion of *gea* ('earth' in ancient Greek), such as a block, a neighbourhood, a city, a region, a river basin, a continent and so on. Maps can be made by one person or can be the collective product of many individuals who agree upon a set of representational conventions (what has to be represented and how). Maps can be sculptured on stones or sketched on papers. Today, map-making is increasingly going digital via specific vectorial drawing software or, more often, via software packages classified as geographic information systems (GIS), which emerged in the sixties from the merging of cartography, statistical analysis and database technology. This entry discusses different approaches to map-making, characterized by different assumptions and goals, with the aim of identifying the important role that map-making can play within an action research process.

Euclidian, Phenomenological and Relational Maps

Two major paradigms can be identified in the history of map-making that are still very much present today. The *Euclidian-Newtonian paradigm*, which sees maps as objective representations of the past, present or future geographical spaces, has been developed by expert map-makers and has converged into the development of the GIS technology. Almost all map experts and GIS technicians would agree with the unavoidable truth that 'the map is not the territory'; however, in pronouncing this famous line, the Polish American scientist and philosopher Alfred Korzybski wanted to warn his audience that many do confuse representation with reality. GIS, with its ability to store and overlap a theoretically infinite amount of data, has in many ways reinforced the idea of the possibility of objective representation and even the hope that the map can be objectively enriched ad libitum until it borders reality.

A parallel *phenomenological* tradition sees maps as *subjective* representations of physical *relative* spaces. Within this perspective, 'facts' or 'data' are not self-selective or self-validating; map-makers choose what to

map and why depending on their goals, value systems, cultural background and so on. This tradition has mostly developed outside scientific disciplines and is very much embedded in the way 'non-expert map-makers' deal with maps. However, beginning in the twentieth century, researchers have explored the subjective meaning of maps, drawing from continental phenomenology to study the relationship between people and places. Within this perspective, the concept of 'place' is often used in lieu of 'space' to indicate a geographic extension with a *genius locus*, acknowledging the interconnection between its physical and non-physical (emotional, symbolic, cultural, etc.) dimensions.

For centuries, *Euclidian* and *place-oriented* map-makers have had very little in common and also very little exchange. However, recent theoretical shifts, postmodernism in the philosophical realm and complexity theory in the scientific debate, together with the 'cultural' and popular diffusion of web-based GIS technologies, are pushing towards a convergence of the two traditions, deepening researchers' understanding of the transformative power of every map. In his 1970 memorial lecture on Korzybski, Gregory Bateson addressed the question 'What is it in the territory that gets onto the map?'. He noticed that, no matter how objective one tries to be, what gets onto the map are not 'objects' but the 'differences between objects'. Those differences (what Bateson calls information) have also the capacity of connecting the map-maker's mind (which could be intended as either an individual or a collective 'mind', indicating a social 'system') with the mapped outside. The information, going back and forth, modifies both the map-maker and the surrounding environment. In other words, map-making can affect both the mapping subject and the mapped space.

Map-Making and Action Research

From a Foucauldian perspective (i.e. 'power is knowledge', power affects the way knowledge is shaped), maps are shaped by powers to influence the way the world is perceived and, consequently, how it is changed or managed. For centuries, 'official' thematic maps have been used in support of powerful political visions and of top-down decision-making: Maps of 'blighted areas' are, for instance, used by policymakers all around the world to justify programmes for forced relocation of powerless communities in order to allow profitable urban redevelopments just like maps of 'environmental hazards' are used to justify programmes for deep alteration of natural topography and ecosystems.

Vice versa, from an emancipatory perspective (knowledge is power), map-making can 'make the invisible visible'. This is not just because 'new things appear in a new map' and can communicate to the

outside a 'different message'. The empowering effect is mostly connected to the process of map-making: A mapper can learn to see things in a different way and feel empowered to act in order to change them (as confirmed by the frequent therapeutic use of map-making by psychologists). This is even more true when map-making is carried out as a collaborative endeavour (e.g. community mapping, participatory mapping, community-based mapping, etc.): The act of locating and sizing issues and hopes on a map implies a process of value sharing among individuals that then can strengthen their sense of community and/or their awareness of the interdependence between humans, other living species and natural resources (e.g. bioregional maps). In an action research perspective, map-making can help individuals become a 'political collective subject', who are then more likely to rise and stand behind political initiatives and processes of social change while acquiring the critical technical knowledge that might allow them to self-manage the change.

MARINO, DIAN

'Be passionately aware that you could be completely wrong'—a favourite saying of the educator, scholar and artist dian marino (b. 1941), if an odd sentiment for a scholar. But marino was a unique scholar who combined her teaching, research, theorizing and art practice in a seamless, if often messy, praxis. Her playful approach to this praxis (hinted at by her choice of

using lower-case letters for the initial letters of her name and surname—inspired by a love of e. e. cummings' poetry) was one deeply informed by her understanding of the ways in which power and hegemony structured and regulated the regimes of knowledge making in which she found herself participating. Her practical and theoretical contributions to fields of environmental and popular education, participatory research and community art have inspired generations of students and activists—first, over the 30-plus years of her own teaching (the last 10 years of which were based at York University's Faculty of Environmental Studies in Toronto, Ontario, Canada) and then in the 20 years since her untimely death in 1993 (after living with cancer for many years). Her influence was also spread around the world through her participation in the international adult education community from Finland (teaching factory workers) to Indonesia (working with people who lived in slums and scavenged for a living), to inner-city Toronto (working in literacy with immigrant women) and more.

Born and raised as dian coblentz in Milwaukee, Wisconsin, she reflected on her formation as artist and educator, acknowledging that having a mother who was university educated and a father who was not left her feeling not wholly of the working class and with her sense of herself as not like everyone else, and ill at ease as a result.

This feeling of being 'ill at ease' reveals a critical and self-reflexive consciousness that marino applied equally to herself as educator and artist and to the world at large in which she participated—often as a disruptive force both at the level of both playful resistance to and dissident theorizing of dominant/hegemonic power. marino's capacity to critique the ways in which dominant notions were trained into people, while informed strongly by her understanding of the concept of hegemony as developed by the Italian Marxist and journalist Antonio Gramsci, is one that she developed by first applying these theories to her understanding of herself. For example, one of the questions she urged her students to ask was 'Where did I learn that (attitude, behaviour, idea), and whose interests are served by this?', marino applied this thinking to her understanding of her own formation as an artist. She remembered that as a young girl, she gave her brother a birthday present of a large sheet of white drawing paper—something that was of great value for her and that she naturally thought would be deeply appreciated as a gift. But when her brother used the gift by drawing nothing but a small spider hanging in the upper-left corner of the paper, marino was incensed. Her initial impulse of indignation that a page that could be a canvas to abundant drawing (which is what she would have done) was used so sparingly was re:framed

(a visual metaphor, of course, and one that is troubled by the insertion of the colon, which is a punctuational politics) in later life with her lenses of artist and counter-hegemonic theorist as an act of brilliance—her brother, regardless of deliberateness, reframing the ‘unused’ white space of the page to lend tremendous power to the austere and singular image of a small spider.

This critical self-reflection, practised throughout her career, from studying at Immaculate Heart College in Los Angeles, California—where she was a student of the famed American artist and teacher Corita Kent—to teaching at a primary school in inner-city Los Angeles, to her work in Toronto and at York, is one that she developed into powerful tools for education and participatory research rooted in an analysis of hegemony. marino understood hegemony as having several aspects, beginning with a complex structure and process of coercion and consent—coercion exercised by a coalition of ruling-class interests to win consent from a population—and including the acceptance of the naturalness of a society structured to benefit the few at the expense of the many, and that, given this common-sense belief that such a structure and process is natural, persuasion by these hegemonic interests is almost always all that is needed to win consent.

marino developed, adapted and applied numerous visual art techniques in her teaching and participatory research. Many of these are documented in her posthumous collection *Wild Garden: Art, Education, and the Culture of Resistance*, which remains a popular resource and teaching tool.

marino’s praxis included theorizing the ‘cracks in consent’ through which a language of resistance could be spoken and enacted. Domination, as she would say, is never 100 per cent. There is always resistance as well as the possibility of expanding that resistance in the interests of people and communities resisting oppression of all forms. A key piece of her praxis was the notion of ‘re:framing’, echoing e. e. cummings, which signifies the tricky and playful aspects of resistance.

MARTÍN-BARÓ, IGNACIO

To many, Ignacio Martín-Baró was a personal friend, a colleague, a mentor, a peer and lots of fun. Perhaps,

in large part, because he was a Jesuit priest as well as a social psychologist at the time of his murder, he has been described by many as a martyr. He has also been acknowledged by the psychological establishment—some of whom shunned him and his work when he was alive—as the ‘father’ or ‘founder’ of liberation psychology. Yet the danger of putting someone on a pedestal, honouring him for his life and work, is that one loses sight of the ‘human side’—and, even more important, of the challenges his life and how he was killed—present to those who survive him. This biographical sketch seeks to reflect on his legacy for the critical praxis of psychology and action research today.

Ignacio—or Nacho to many of his friends and colleagues—the fourth of six children born to Francisco J. Martín Abril and Alicia Baró, was born on 7 November 1942, in Valladolid in northwestern Spain. He entered the religious order of the Society of Jesus on 28 September 1959, having completed his high school education at the Colegio San Jose in Valladolid. In addition to excelling at his studies, his talents as a magician were often sought to entertain local children. His ‘lighter side’ would be noted by Salvadoran peasants and psychologists alike who recognized and celebrated his humour, his guitar and his voice; he was the life of many late-night and weekend gatherings in El Salvador and beyond.

Martín-Baró completed his early training as a member of the Society of Jesus in El Salvador and then studied philosophy in Bogota, Colombia, and theology in Belgium before completing a psychology degree at the University of Central America, José Simeón Cañas in San Salvador in 1975 followed by a master’s and doctorate in social and organizational psychology in 1979 at the University of Chicago.

He then returned to the University of Central America in San Salvador, where he taught and did research while also holding various administrative posts, including Dean of Students, chair of the Psychology Department and Vice Rector for Academic Affairs. He also served on a variety of administrative committees and boards within the university, was the founder and director of the University Institute of Public Opinion (known by its Spanish acronym, IUDOP) and was an editor of the university’s publishing press. Beyond El Salvador, he served on the editorial board of a number of professional journals and was a member of the American Psychological Association and the Interamerican Society of Psychology, where he served a term as vice president for Mexico, the Caribbean and Central America. In addition to his academic work, Martín-Baró served as a weekend pastor to several small villages, including that of Jayaque.

Martín-Baró adopted Salvadoran citizenship and lived and worked among the Salvadoran people from 1966 until his death, accompanying them in their

struggle for self-determination. In addition to his critical analyses of Euro-American psychology, he passionately challenged US psychologists to analyze their government's role in El Salvador, writing and speaking about US economic and military aid to the Salvadoran government's war against its own people and emphasizing the importance of dialogue between the government and the guerrillas towards a negotiated settlement to this ongoing armed conflict. He spoke within and beyond El Salvador of the importance of economic justice and of the need for structural changes within his adopted country.

On 16 November 1989, Martín-Baró, five of his Jesuit colleagues, their housekeeper and her child were brutally assassinated by the US-trained Salvadoran Atlacatl Battalion, an elite unit of the Salvadoran Army. They were 8 of the more than 75,000 people murdered—and countless others who 'disappeared' or were displaced—between 1979 and 1992, the years of El Salvador's bloody armed conflict. A United Nations Truth Commission estimated that the right-wing, military-led government committed approximately 85 per cent of these gross violations of human rights, while left-leaning guerrilla groups (Farabundo Martí National Liberation Front), including farmers, teachers, former priests, women and union activists, were responsible for about 5 per cent of them, with responsibility for the remaining 10 per cent unable to be determined. The US government sent approximately \$6 billion to this tiny Central American country during the course of this civil war, making El Salvador second only to Israel as the highest recipient of US aid during that period.

Author and Advocate

Martín-Baró was a prolific public speaker, editor and author, publishing close to a dozen books and over 100 articles and book chapters. Most of his work is available only in his native Spanish, with the exception of the excellent volume edited by Adrienne Aron and Shawn Corne, *Ignacio Martín-Baró: Writings for a Liberation Psychology* (and published in 1994 by Harvard University Press), which includes 12 of his articles translated into English. Among his most widely known and used books are two college texts on social psychology whose English-language titles are *Action and Ideology* (1983) and *System, Group, and Power* (1989). In these texts, Martín-Baró critically engaged US and European social psychology, describing parameters for a psychology based on the Salvadoran majority's experiences and understandings. Rather than apply theories derived from the North, he sought to subvert this thinking, arguing that it failed to explain or respond to the lived experiences of the majority world. Despite these important contributions, which are frequently interpreted as part of

his effort to 'liberate psychology', he was not focused solely or even primarily on critique but rather on developing a praxis, that is, a set of reflexive action-reflection processes, which would contribute to a more just and equitable El Salvador.

The survey was one professional resource with which Martín-Baró was familiar. He sought to subvert the institutional lies propagated by the Salvadoran and US governments by documenting Salvadorans' opinions 'from the bottom up'. Themes incorporated in the surveys he designed ranged from health and housing to the highly charged problems of democracy, structural economic inequalities, war and peace. To sustain and institutionalize this work, he developed the independent public opinion polling organization, University Institute of Public Opinion, an effort all the more extraordinary given the prevailing political-military conditions in El Salvador in 1986. Concerned about the abuses of surveys by governments and some commercial enterprises, he forged ties with colleagues in the region to form the Central American Program of Public Opinion, developing a professional ethical code for the conduct of survey research in Central America.

Martín-Baró's work as a surveyor of public opinion, that is, of the people's rendering of their own experiences, was central to his struggle to know, to speak about and to preserve reality as experienced by the Salvadoran people. He noted that one of the objectives of psychological warfare was to systematically attack survivors' ability to distinguish what is true from what is not true, their own account of their lived experiences from the government and economic elite's 'official story'. Profoundly abnormal experiences such as 'disappearances' had become everyday occurrences, experienced by the majority of Salvadorans but denied by those in power. Ignacio coined the phrase *normal abnormality* to describe the polarized realities of everyday life, wherein murders, disappearances, extreme poverty, rape and so on were either openly denied by the government and the media or enshrouded in an institutionalized lie redefining them as, for example, part of a 'process of democratization'. In public talks and personal interviews within and beyond El Salvador, Martín-Baró countered this dominant discourse, arguing that the evidence he was gathering through his survey research and his own lived experiences—including having survived multiple death squad attacks—confirmed that El Salvador was indeed a country at war—a war supported by US tax dollars. Further, Martín-Baró asserted the importance of understanding the root causes as well as the effects of war on the people of El Salvador within their historical and social contexts. He challenged a growing tendency among psychologists working with a growing number of war veterans and civilian survivors to reduce war's psychological effects

to individual pathology or stress, that is, post-traumatic stress. Without negating the particular ways in which war marked individual lives, he focused psychology's attention on human sociality, describing the deterioration and rupture of social relationships during armed conflict and war's erosion of our collective capacity to tell the social history of a people. He described war as generative of 'psychosocial trauma', a construction which he was among the first to use in characterizing war's psychological and sociological effects.

Shortly before his assassination, Martín-Baró had turned his attention to the children and youth of El Salvador, particularly to those hundreds of thousands who had been directly affected by the war during the previous 9 years. He wrote that the polarization of El Salvador's ongoing conflict was socializing the next generation into adopting violence as the only possible response to disagreements or conflicts, constraining youth's life choices to opting for one of two opposing militarized forces, that is, the Salvadoran military or the FMLN (Farabundo Martí National Liberation Front). As he analyzed these realities, Ignacio also secured funds to open a clinic to work with children and their families and initiated a four-country action research project, which sought both to understand more fully the impact of the war on Salvadoran and Guatemalan children and youth in Chile and Argentina and to develop specific psychosocial resources that drew on the creative arts for accompanying children and their families in zones of armed conflict and under dictatorships.

One Among Many: A Challenge for Twenty-First-Century Psychology

Many have sought to extend the work cut short by Martín-Baró's murder. There are innumerable institutes and courses of liberation psychology within Latin American universities and a biannual meeting of liberation social psychologists who also host a large listserv. There is a growing interest in his work in the English-speaking world, facilitated by the writing and applied work of the feminist psychologists Simone Linderfor (Germany), Geraldine Moane (Ireland) and Michele Fine and Mary Watkins (USA), among others, and by the work of Mark Burton (UK) and the English-language network www.libpsy.org. A small group of Martín-Baró's colleagues formed the Ignacio Martín-Baró Fund for Mental Health and Human Rights (www.martinbarofund.org) to further the goals to which he dedicated his life. Small grants support progressive, grass-roots groups throughout the world who are challenging institutional repression and confronting the psychosocial consequences of gross violations of human rights and other structural injustices and inequalities in their communities.

During his 9 years as a psychologist, university professor and administrator and parish priest in El Salvador, Ignacio wrote and spoke regularly about the profound challenges to the practice of psychology in the context of armed conflict. He acknowledged that most Salvadoran psychologists (approximately 700 in 1987) passively supported the government; some, including former students, actively participated in the armed forces, designing and carrying out psychological warfare. He spoke of himself as one among a very small number who challenged the status quo, arguing that such psychologists were forced to seek new models, to find different approaches to their work. His life and death challenge all psychologists to be among those with whom he numbered himself. US-based psychologists working in his wake are challenged to extend the reflexive, action-reflection model he initiated towards (a) de-ideologizing the official stories perpetrated by their governments and economic elites, (b) denouncing the economic chasms separating rich and poor and the hyper-wealthy, (c) undoing institutionalized racism, whereby brown and black bodies are more likely to be deported, incarcerated or killed than to gain entry into higher education and (4) deconstructing the militarization of everyday life, its anti-terrorist rhetoric and the erosion of previously cherished civil liberties. Martín-Baró's legacy challenges researchers to practise a psychology that subverts the established lies of the times through research, teaching and praxis that accompany the majority population as they develop a *people's psychosocial praxis*, that is, a psychology of, with and for the twenty-first century.

MARXISM

Marxism is a critical theory primarily concerned with how the problems of a capitalist economic system encompass the social relations of the working class. Marxists identify these problems as pervasive and diverse, influencing not only general labour relations and issues regarding the means of production but also a wide variety of environments and interactions. Serving as one of the first critical theories, Marxism is both a theoretical framework and a political movement with substantial applicative possibilities and has become well established in numerous academic disciplines, including history, philosophy, economics, sociology and education. Action research also possesses its own connection to Marxist theory, actualizing many of Marxism's central tenets while transporting it into new methodological directions.

History

Marxism's namesake famously claimed that he was not a Marxist, yet Karl Marx' contributions to the framework are integral, and scholars continually return to his texts in order to uncover new perspectives on a movement that began in the 1840s. Marx' initial foray into theory was largely a philosophical one, typically characterized as a melding of G. W. F. Hegel's dialectics and Ludwig Feuerbach's materialism. The synthesis of these two frameworks generated a cornerstone of Marxism, dialectical materialism, which can be defined as a progressive tendency of the physical world to work through internal contradictions and to achieve a state of maximum efficiency. Marx applied dialectical materialism to history and economics in order to explain how the social and political order came into being, primarily through the class struggle between the proletariat and the bourgeoisie (the worker and the capitalist). Evolving from antiquated feudalism, Marx charted capitalism's development with a keen critical eye, arguing that concentrations of capital would fall into the hands of an elite class who would exploit a

much larger population of workers in order to maximize profits and expand industry throughout the world. While capitalism would deliver an abundance of goods ripe for consumption, its unstable, exploitive nature would also create a series of substantial drawbacks for the worker, including increasing economic inequality, periods of unemployment and alienation from one's labour and fellow workers. For Marx, the most effective way to end this oppressive exploitation was for the working class to take back the means of production through revolution. With public ownership of property and capital, capitalism would be usurped by a communist economic system, allowing for greater economic equality and the possibility for human beings to realize their potential.

After Marx death in 1883, Marxism would fracture into several different strands and factions, each emphasizing different elements of Marx' thought while supplementing it with other theoretical frameworks. Most notably, Vladimir Lenin and Leon Trotsky would employ Marxist theory to power the 1917 Russian Revolution. Appropriating Marxism's revolutionary potential and proletariat-centred philosophy, Leninism and Trotskyism stand as the strongest applications of Marxism on a global scale. Unfortunately, the Soviet Union's transition from capitalism to socialism required a form of governmental dictatorship to act as an intermediary, which instead of passing power to the worker, only became more oppressive. This reality, coupled with the collapse of the Soviet Union, stigmatized Marxism for many people, even if Soviet Marxism strayed from many of Marxism's central tenets.

Despite this stigmatization, many theoretical variants of Marxism represented novel representations of Marx' critique. The Frankfurt School theorists worked closely with Marxist theory to forge new critiques of capitalism that ventured outside purely economic realms into those of culture, technology and communication. Other Marxist theorists, like György Lukács, directed Marxist theory inward, writing focused critiques of class consciousness, which relates to Antonio Gramsci's Marxist-inspired theories regarding hegemony. These theorists worked to fill in important gaps in classical Marxism and further explain how capitalism's influence exists not only in the factories, but also in government, the media and the mind of the worker. Finally, Marxism also was profoundly influential in the formulation of postmodern and post-structuralist philosophy. Many of these theorists, like Michel Foucault and Jean Baudrillard, held close initial ties to Marxism that are still prevalent in their later work. Granted, much of postmodern theory proves somewhat adversarial to Marxism due to its status as a grand meta-narrative overly concerned with notions of class. Nevertheless, theorists such as Frederic Jameson and Slavoj Žižek have employed

Marxism in social, cultural and literary fashions that rival postmodernism. These new formulations of Marxism transport the theory into new directions, ensuring its continued relevance in scholarly discourse.

Characteristics

The critique of capitalism is at the heart of Marxism and holds numerous theoretical implications pertinent to any number of disciplines. From a Marxist economic perspective, capitalism is an unstable system rife with contradictions such as capitalism's lauding of competition while often giving way to monopoly. Another contradiction is that to maximize profits, capitalists must limit workers' wages while having these same workers consume the commodities produced in order for the company to make a profit. Moreover, there is a measure of anarchy inherent in capitalism that compels industry and corporations to grow and produce despite societal conditions that do not allow such growth to be economically feasible, which leads to stagnation, recession and unemployment. Marx' analysis was the product of intensive decades-long research through which he continually refined his theory. The culmination of these efforts is most fully realized in his three-volume, unfinished treatise *Capital*, which many scholars regard as one of the most important analyses of capitalism ever composed. Within this text, the interworking of capitalism is exposed as theories regarding the labour process unfold from numerous vantage points, creating a critical account of how the worker is exploited for the sake of maximizing profit.

The work performed in *Capital* has served as both a uniting force as well as a point of contention for many Marxists. Many Marxists or Marxist-oriented theorists have taken Marx' critique into different directions, modernizing it or applying its theories to other forms of capitalist oppression. Henry Braverman's *Labor and Monopoly Capital* serves as a powerful example of employing Marxist theory to analyze the labour process, particularly in the field of management, which was only beginning to develop in Marx' time. Within Braverman's work, the gradual process of deskilling reduces workers' autonomy until they are rendered obsolete by the labour system. Other such macrolevel critiques of capitalism, such as those offered by Lenin, link imperialism and war to political and economic acts fixated on expansion, placing roots in new markets and harvesting resources.

As previously mentioned, a critique of capitalism pertains not only to large factories and corporations but also lies within the consciousness of individuals. This is where correlating discussions of ideology, false consciousness and alienation operate as pivotal themes in Marxist thought. Marx wrote about the

nature of ideology as a superstructure that influences the material base of the political economy. Capitalists' interests dictate the ideological character of a population, such as a stalwart belief that by merely working hard, a worker can advance in capitalist society. Such ideology becomes embedded into the worker's mind as false consciousness, a means of inward control that enables capitalists to exploit workers with little coercion. Alienation also operates as a disciplinary mechanism in which workers cannot band together in order to combat this oppression. Separated from the product of labour and from one another, the alienated workers embody the divisive and dehumanizing tendencies of capitalism. Certainly, the individuals often possess a consciousness that is keenly aware of capitalist ideology and employ, through education and collaborative action, means to upset this form of control. However, the degree to which ideology is entrenched into the fabric of contemporary existence hinders revolutionary consciousness and action as the dialectical relations between base and superstructure, the physical world and ideology, inhibit movements that disrupt the mode of social reproduction.

However, despite this weakened position in capitalism, the proletariat acts as the true subject of history and the primary lever of social change. For Marx, history is dominated by class struggle. Capitalism's evolution and dynamic growth come at the continual cost of the proletariat; yet as capitalism grows more unstable and the numbers of the working class increase along with its unrest, the formerly marginalized population will usher in capitalism's demise. Therefore, the working class becomes history's true focus, representing a grand reversal of narratives revolving around the rich and the powerful. The proletariat has power, but must choose to use it. This reality nullifies characterizations of Marxism as overly ridden in economic determinism and dialectical materialism as negligent of people's autonomy. True, Marx afforded substantial emphasis to social structures that often prevent people from realizing their true potential. Nevertheless, the individual and collective choices regarding how people participate within a social or economic system will lie in their own hands.

Ultimately, it is through the proletariat that the Marxist endgame to capitalism unfurls: revolution and communism. These two fundamental characteristics of classical Marxism are often misunderstood primarily due to their application in the 1917 Russian revolution and the rise and fall of communism in the USSR. Undoubtedly, Marx perceived revolution as a possible conveyor to capitalism's end, yet the violence seemingly inherent within the revolutionary process was a secondary and perhaps even unnecessary element. Instead, the crucial aspect to revolution, for Marx, was

that it would represent the ultimate manifestation of proletarian will, and due to the immense power produced when the workers banded together, there would be no other recourse for the oppressive social order but to collapse. Historical portrayals of revolutions emphasize war and bloodshed, and while violence may not have been excluded from Marx' revolutionary framework, Marx also contended that revolutions could occur peacefully supplemented by a series of social reforms.

After revolution, communism would serve as both a new economic and a governmental system, and like revolution, Marx' conception of communism is more complicated than most are led to believe. True, communism shares fundamental elements with the popular conception: public ownership of property and the means of production along with the equal distribution of economic and political power; however, like Marxist revolutions, there is a crucial philosophical undercurrent to communism as both a historical and an ontological process. Communism is as much a historical transformation as it is a political one, representing the abolishment of the old order in favour of one that reflects the will of the people. Communism also represents a system where human beings can truly flourish, for when the fetters of capitalism are removed, individuals from all walks of life can pursue their own interests and realize their potential. The final important aspect of communism is its democratic nature. By instilling economic equality, communism transcends democracy rooted solely in politics to truly reflect the will of the people. Unlike Soviet communism, Marx' theory of communism is a profoundly participatory one where citizen power is maximized and the general populace holds a great stake in the country's decision-making process.

Marxism and Action Research

Marx argued that philosophers should not only interpret the world but also change it. This sentiment holds just as true for action researchers. Indeed, the Marxist concept of praxis serves as a fundamental precursor to many action research initiatives. Praxis is a concept linking the crucial areas of theory and practice. For many Marxists, to simply advance a theory regarding a social or economic situation is not sufficient. Ideally, every theory has an applicative functionality that can be as large as igniting revolutionary activity or as small as improving working conditions for a singular group of people. Praxis is linked to Marxist materialism, where concepts such as culture and economics do not occur in a vacuum but are influenced by the material conditions of their environment. The same holds true of theory, and as action researchers, generating research merely

for descriptive or speculative purposes is fundamentally lacking. Action researchers are thus empowered by their own form of praxis, melding together their expertise with a desire to change the world at either a large or a small scale.

From a philosophical standpoint, action research holds possibilities regarding dialectics and historical materialism. Action research is, in many senses, a dialectical process. First, the action research cycle is an open one tilted towards perpetual incompleteness. Like dialectics, where the dialectical synthesis is continually reconfigured, action research ideally does not stop when the study is over and the researcher has collected the data. Instead, the process continues, so participants are empowered to such a degree that they can carry the research on their own shoulders in the directions of their choosing. Moreover, just like Marxist dialectics, action research is embedded in the social, cultural and political environment where the study takes place. Action research is a political methodology; it does not occur in a laboratory, but it is dependent on the material conditions of the research location. This links back to the historical materialism inherent in Marx' thought, where theories were reflective of material conditions and possessed historical or contemporary implications. Indeed, action research's conception of history shares a number of similarities with a Marxist one in terms of materialism, being critical of the dominant social order and being concerned with the narrative of the oppressed. Through these crucial linkages, action research proves indicative of Marxist traditions.

Furthermore, more so than any other research methodology, action research also possesses a great deal in common with Marx' conception of communism. As previously mentioned, Marx saw communism as a participatory process where everyone would have an equal voice in the process. Naturally, this correlates highly with Participatory Action Research, where a similar theory regarding meaningful political participation serves as the primary engine driving the research process. Communism and action research are not only non-hierarchical structures, but both progress a step beyond and act as political and research approaches that actually increase the power of those populations who would be neglected otherwise. Concerning this point, it is important to recognize that the democratic, collaborative approach indicative of both concepts is applied not only for the sake of reversing the status quo but also because these approaches are intensely pragmatic, despite popular contrary claims. Incorporating as many people as possible in the political or research discussion holds legitimate and profoundly beneficial implications in forging a better society.

In realizing the numerous connections between Marxism and action research, many action research

projects are directed towards explicitly Marxist aims. Participatory action researchers often perform projects with workers to improve some facet of their working life, including reducing stress or strengthening their voice. Another form of Marxist-inspired action research consists of projects situated from a social class perspective, which again can be focused towards empowering the working class. Certainly, action research's tendency to work with marginalized populations reflects a Marxist world view. Capitalist exploitation is not limited to problems concerning labour but rather comes in many forms that action researchers can seek to resolve. Problems as diverse as exploring the corporatized nature of schools, analyzing violence in an urban community and assisting people in developing countries where capitalist oppression is at its most hostile can all be included in a Marxist framework. Thus, Marxism allows for profound inclusivity in terms of potential action research studies that researchers can perform.

There is also revolutionary potential in action research, and this potential harkens back to a similar revolution that Marx so hopefully described. Changing the world one study at a time, action research fulfils a variety of revolutionary prescriptions related to Marxist theory. Action researchers' continual work with oppressed populations has been well emphasized, but the critical current running through action research echoes Marxist initiatives. In an action research context, research operates as a critical tool against capitalist exploitation and oppression. The researcher's familiarity with theory and methodology enables that researcher to critique capitalism from a credible position that is subsequently adopted by participants. It is important to recognize that a Marxist revolution is not purely a physical one but an epistemological one as well. Through their efforts, action researchers build a critical body of knowledge accessible to others interested in similar work. Moreover, action research can be employed to deconstruct capitalist ideology, hegemony and false consciousness, thus serving as a pivotal starting point in the revolutionary process.

Finally, like action research, Marxism has strong ties to critical education and pedagogy. As an educator and an exemplar for many action researchers, Paulo Freire worked primarily in a Marxist tradition. His efforts regarding consciousness-raising and employing education as a critical force represent endeavours to eliminate false consciousness. Other Marxist education scholars have performed similar work in schools across the world, producing theory and research regarding capitalist oppression rooted in education. Classroom-based action research holds a similar stake in this critical agenda. Embedded in the classroom and working with their students, classroom-based action researchers

can perform a variety of studies that work to raise the social consciousness of their students or reduce corporatized or commercial agendas in schools, so that their students do not fulfil the capitalist destiny of becoming uncritical consumers and alienated workers.

With these numerous initiatives, the connection between Marxism and action research is strong. Appropriate in the community, the factory and the school, Marxist-inspired action research serves as a powerful research process capable of accomplishing empowering and even revolutionary aims. Despite the rapid progression of capitalism since Marx' time, his theories still hold a relevance that compels researchers to return to them in order to launch new critiques of capitalism. In doing so, the final similarity shared by Marxism and action research reveals itself: that of hope. Although many focus on the prevalent Marxist rhetoric of capitalist domination, Marxism is an optimistic philosophy that continues to envision a better future for all people, and action research represents a crucial process through which this better future can be realized.

MAYA WOMEN OF CHAJUL

Mayan *ixil* and *k'iche'* women participated in a series of Participatory Action Research (PAR) processes in the wake of more than 36 years of armed conflict in Guatemala. Specifically, creative techniques—including

drawing, storytelling and dramatic play—were combined with Mayan beliefs and practices and more traditional participatory research strategies including interviews, oral histories and photo documentation and elicitation to tell the story of the gross violations of human rights in a remote corner of Guatemala in the 1980s. Feminist-infused PAR and PhotoPAR were deployed as resources for narrating survival and resistance and re-threading community towards creating a better life for survivors and their families. Selected processes are discussed towards exemplifying action research as a resource for those who seek to accompany survivors of humanitarian crises, including armed conflict.

Historical Background and Contemporary Challenges

San Gaspar Chajul is one of three municipalities in the northern province of El Quiché, Guatemala, a country where 43–60 per cent of the 14–15 million inhabitants are indigenous, mostly Maya. The median age is 20 years, with a life expectancy of 71 years. Approximately 54 per cent live on about \$3 per day; some suggest that in rural areas such as Chajul, that figure rises to over 80 per cent. Despite recent increases in educational levels among today's youth, a large percentage of adults are illiterate, with estimates of only 39 per cent literacy among indigenous women between 15 and 64 years of age, many of whom are monolingual, speaking one of the country's 21 indigenous languages but not the country's official language, Spanish.

Indigenous people were evangelized and forced into servitude under Spanish colonization, which endured until the country achieved independence in 1821. Liberal reforms in the 1870s introduced coffee on a large scale, plantation agriculture became the norm and inequalities in wealth escalated. A democratic revolution in 1944 brought a reformist government to power that was overthrown in 1954, with the US Central Intelligence Agency playing a major role and installing military dictators supported by a powerful oligarchy.

In the 1970s, the military unleashed widespread counter-insurgency violence against a confluence of revolutionary guerrillas and social movements who threatened their power. After nearly four decades of armed conflict, the Guatemalan National Revolutionary Unity and the Guatemalan government signed Peace Accords in 1996. The Catholic Archdiocesan report *Guatemala Never Again* (REMHI) and the report of the UN-brokered Commission for Historical Clarification (CEH) estimated the death toll of those years to be between 130,000 and 200,000, with an additional 50,000 'disappearances', at least 1 million internally displaced persons, 100,000 officially recognized refugees and 200,000 orphaned children. The

CEH concluded that the acts of the Guatemalan state against the indigenous people constituted genocide.

Over one third of the approximately 600 documented massacres during the armed conflict occurred in the Quiché region. The military and their forcibly conscripted civilian patrollers occupied the town of Chajul, terrorizing the local community, raping young girls and women and, among many other atrocities, hanging a woman in the town square whom they accused of having lured the army into a guerrilla attack. The REMHI report identified at least five massacres in the vicinity of San Gaspar Chajul in the early 1980s—four in the village of Chel and the fifth at the La Perla Plantation.

Despite regularly held elections since 1985, democracy has continued to erode driven by a re-functionalized plantation agricultural system, persistent concentrations of wealth and a government that is corrupt and unaccountable. Drug and human trafficking as well as organized crime are widespread, with women bearing the brunt of such violence in a context described by human rights activists and feminist scholars as femicide. The police are ineffectual, and a former military general accused of human rights abuses during the war now serves as president. Despite this, many, including the Maya women of Chajul, are engaged in ongoing efforts to seek truth and to bring human rights abusers to justice.

Thirty Years of Community-Based Collaboration and Solidarity

A small group of surviving Maya ixil and k'iche' women sought to create a better future for themselves, their families and Chajul and its villages in the 1990s. Their initial impulse was to gather 'as women', within and across ethnic, linguistic, political and religious differences. They sought resources to build a corn mill, thereby reducing the 4- to 6-hour/day task of hand-grinding corn for tortillas, the staple of daily meals, and generating time and surplus income to develop educational programmes for their children, whose monolingualism and extreme poverty prevented their access to the local Spanish-language public education. Over time, a small group of six grew to an organization of more than 100, the Association of Maya Ixil Women—New Dawn (ADMI). Projects included ongoing creative workshops for women survivors, a corn mill, an ixil-language educational programme for children, a community store, a community library and, eventually, a small revolving loan fund that supported local economic development initiatives.

Despite their multiple and varied experiences of the war's atrocities, many women in ADMI hesitated to give their testimonies to REMHI and the CEH.

Yet, in the summer of 1997, they embraced the idea of developing a local testimonial process, building on Caroline Wang's Photovoice processes from rural China. Through participatory photography, interviews and storytelling, they sought to document Chajul's 'community story' of the armed conflict, their survival and ADMI's emergence.

PhotoPAR as a Resource for Re-Membering and Re-Threading Community

Twenty k'iche' and ixil women joined 'outsider researchers' and collaborated for nearly 3 years to create a PhotoPAR process chronicled in *Voices and Images: Mayan Ixil Women of Chajul*. They broke silences and stereotypes, becoming some of the first k'iche' and ixil women photographers and activist researchers. They developed skills as interviewers through telling personal stories to each other, learning of guerrilla and military violations and then travelling to distant villages of returning refugees who chronicled massacres and the extreme poverty of years of hiding in the mountains. The horrific story of *The Hanged Woman* was chronicled by the mother of the woman who was hanged—and then analyzed and reanalyzed through the participatory research process. Women who had sought refuge in Mexico, the capital city or the mountains listened to those who had remained in Chajul, alongside whom they now travelled to pull water from the well, never imagining the horrors their neighbours had survived. In focus groups with participants 5 years after the final book was presented to the Guatemalan and international communities, some women acknowledged that picture taking, interviewing and collaborating with each other in analyzing the phototexts had given them the courage to ask about a father's disappearance or a sibling's assassination. Thus, the processes of re-membering and of generating individual and collective stories—and sharing them with the local community—contributed to reducing tensions in Chajul and to enhancing some participants' understanding of the root causes of the armed conflict, and the challenges of post-conflict transitions.

Separation and Survival: Extending Women's Community

Despite the multiple successes identified and celebrated through the PhotoPAR processes, the Women of ADMI were unable to sustain their organization in the midst of internal conflicts that mirrored many of the political tensions in the post-war period. Within 2 years of the book's publication, they separated into two organizations, committed to sustaining work with women and children. A second organization, the

Center for Mayan Ixil Education and Development, responded to the threats represented by gang violence by shifting their organizing and educational efforts to include young men alongside their work with women. As important, they responded to the requests of those village women who had generously told their stories in the PhotoPAR process. The Center for Mayan Ixil Education and Development has facilitated monthly meetings in approximately 20 rural villages where indigenous women gather to tell stories of survival and learn about their rights. A process evaluation of these village interventions using the creative techniques that characterized the early work of ADMI suggests that despite ongoing and persistent poverty and violence, rural indigenous women celebrate opportunities to gather, to learn about their rights and to share their stories with each other. Their artwork and theatre productions reflect their enhanced self-understandings, self-esteem and agency. A small cadre from among the 20 women who participated in the PhotoPAR project facilitate these workshops through which Maya ixil and k'iche' women of Chajul and its surrounding villages embody and perform a transformed Maya womanhood.

Thus, PAR and the creative arts have been embraced by rural, non-formally educated Maya women alongside their traditional beliefs and practices towards re-threading community in the wake of horrific violations of human rights. Analyses of pictures in small groups offered teaching-learning experiences through which to narrate individual and collective losses. Through dramatic play and theatre, women embodied long-silenced fears and anger and performed imagined future actions that shaped concrete actions that they carried out through their organizations in Chajul and its villages. The knowledge generated from this local praxis now informs others seeking to respond to psychosocial trauma and human suffering in the wake of humanitarian crises.

META-METHODOLOGY

Action research is becoming increasingly recognized as a meta-methodology by which the researcher learns the way into the details and complexity of the situation of interest. As an extension of natural approaches to problem-solving which involve cycles of intention, action and review, Bob Dick has described the essential enhancements gained from an action research approach. These include enhancement of review as critical reflection, greater attention to rigour and theory, care in identifying who else to involve and flexibility to borrow and develop processes as a result of these reflective concerns. Action research as a meta-methodology requires a critical appreciation of methodological underpinnings and implications, and it can enable a more systemic and multilayered inquiry into real-world situations and issues. How different methodologies can be complementary or conflicting in their underlying ideologies is a critical issue which is both long-standing and of continuing contemporary importance. An outline is provided in the following sections regarding questions of pluralism and complementarity and the generative dimension of action research. This is followed by a brief description of some recent applications of action research as meta-methodology from psychological, environmental and educational domains of practice.

Pluralism and Complementarity

Concerns regarding the potential for methodological complementarity have an extensive history of debate. Debate regarding research paradigms and methodological implications has ranged across many disciplinary traditions. All methodological perspectives come with fundamental underpinnings relating to the nature of inquiry and philosophical ideals. A focus on pluralism and meta-methodology seeks to develop conversations around frameworks on interpretation which reflect and respect multiple viewpoints on these underpinnings. Rather than putting up a trivial ‘straw man’ of an opposing position to be knocked down triumphantly, a meta-methodological view enables critical development of a preferred position while maintaining a respect and

recognition of the strengths of other approaches for particular aspects of the situation of interest. A meta-methodological perspective can assist those seeking to overcome differences in methodology and underlying values and keep conversations going across ideological and disciplinary boundaries. Frameworks of interpretation are themselves highly contestable, and so the descriptions below draw upon frameworks associated with action research and systemic literature which have been debated robustly and applied broadly—interpretations that build upon critical systems and David Kolb’s learning competencies. These are presented as examples of potential meta-methodological frameworks that can aid in critical comparison and exposition.

A useful beginning point is to start from a position common to many practitioners of action research. Action research is defined by its intention as a pluralist practice underpinned by a participative world view, seeking to co-construct the process of inquiry and the understanding generated. This is a strong epistemological position, that is, a perspective on the nature of inquiry, and aligns strongly with a constructivist epistemology. A constructivist perspective addresses subjective and intersubjective concerns through seeking authentic representation of participant’s perspectives, through open and honest documentation and cycles of hermeneutic interpretation (i.e. a process of interpreting meaning and context). With an explicit aim of improvement, constructivist scholars such as Yvonna Lincoln identified the criteria of ‘trustworthiness’ as the following: Has a heightened awareness of one’s own constructions been achieved (ontological authenticity)? Has an increased awareness of other stakeholders’ assumptions been achieved (educative authenticity)—or the capacity for prompt action (catalytic authenticity) or the ability to engage the political arena on behalf of stakeholders (empowerment criteria)—or of the extent to which external readers can infer relevance to their own situation (transferability criteria)? These criteria reinforce the importance of a strong epistemological position regarding the role of the researcher and his or her inquiry.

Similarly, within the evolving discourses of systems literature, a key evolving theme has been an increasing need for epistemological awareness, as recently outlined by Ray Ison in his review of systems thinking and practice for action research. Developments in critical system literature since the early 1980s have reflected the emergence of critical systems practice and systemic intervention, which reflect core values of methodological pluralism, improvement and critical awareness. A proposed schema developed early in this debate was the ‘system of systems methodologies’ as a meta-theoretical framework of interpretation to underpin methodological pluralism. Hard systems,

soft systems (or practical action research) and critical systems thinking (or critical action research) were defined in relation to the Aristotelian concepts of *téchnê* (making action) and *praxis* (doing action), and Jürgen Habermas' knowledge-constitutive interests as being technical, practical or emancipatory.

Developing upon this spectrum of interests, epistemological positions range from positivist to post-positivist, interpretivist, constructivist and critical theorist. For each epistemological position, there is a range of philosophical underpinnings, for example, an interpretivist who quotes John Dewey as a champion is likely to hold a pragmatist philosophy, a normative ethic of seeking adaptive problem-solving, an axiology (or theory of value) in problem-solving and an ontology (or view of the world) as a humanist or normative construction. Similarly, a particular epistemological position and associated underpinnings inform the methodological implications consistent with this view, such as their systems view, primary logic used, methodological objective and ideal, criteria of validation and toolkit of methods supported. This type of meta-methodological framework can be used as a modelling space to compare and contrast different disciplinary traditions, as outlined by Roger Attwater (2000).

Action research is sometimes viewed as a subset of social research and has obvious strong methodological precursors that resonate with the epistemological positions of interpretivist and constructivist inquiry. However, similar to the evolving area of critical systems, it is becoming common to view action research as a meta-methodology in its own right. In addressing a social context of inquiry, additional richness may be gained by incorporating analytical and post-positivist perspectives. Alternatively, the social context of the inquiry may have contextual dimensions such as those associated with physiological, ecological or design processes, for which a realist ontology and methodological traditions of falsificationism, hypothesis testing and science are appropriate. Rather than limiting the bounds of inquiry to social dimensions, judicious incorporation of broader traditions can enable a more systemic inquiry.

The Generative Dimension

By taking a meta-methodological stance, action research can seek to assist in the dynamic co-ordination of the insights gained from the application of different methods, tools and logics. The process of inquiry has of itself a generative nature, and it is by this dynamic that engagement in the process hopes to achieve the constitutive elements of action research. As the inquiry engages participants and models of improvement reflecting different world views, a potential is enabled

for a new context-specific framework of understanding to emerge from both the first person perspective of the researchers and the second person perspectives of participants in the inquiry. In this way, action research can facilitate the synthesis and the generation of trans-disciplinary practice, whereby conversations across disciplinary boundaries generate an emergent broader perspective which is inclusive and respectful of the individual disciplinary frameworks. This is not just the realm of synthesis across academic disciplines, as different methods of logic and tools of inquiry are common to any communities of practice, with practices reflecting alternate epistemic foundations.

A relevant foundation for this dynamic view of meta-methodology derives from experiential learning. John Dewey identified that in our adaptive search for diagnosing and addressing social concerns, there are two general ways of grasping knowledge: (1) comprehending as a reflective recognition and (2) apprehending through experimentation with the outside world. David Kolb further developed this into a schema of interpretation and action, adding a dimension relating to how we use this knowledge: Do we apply it to concrete experience or use it to develop more sophisticated models of how things seem to work? This robust schema has been applied in a number of ways to inform our practice of inquiry and critical awareness of competency development. The common dynamic of plan, act and reflect used to describe action research enables a richness of generative development which can be considered as a methodological cascade, with the form and type of methodology used in subsequent steps of an inquiry emerging from previous steps of inquiry, consistent with critical reflection and subsequent adaptive application. Multiple lines of inquiry can separate, build and coalesce as the inquiry gains momentum.

Examples From Psychological, Environmental and Educational Domains

There is a broad and distributed variety of studies that utilize variants of action research in a meta-methodological manner and reflect increasing epistemological awareness. Provided below are examples of the application of different meta-methodological perspectives. The sources are listed in the Further Readings.

A very accessible description of issues of complementary methods has been provided by Mark Burton and Carolyn Kagan in relation to psychological research. Building upon the history of paradigm debates, the authors draw upon critical systems approaches to tease out the substantive ideological and philosophical debate behind the scenes of debates regarding qualitative versus quantitative research. The

authors discuss differences of epistemology (the nature of knowledge) and ontology (the nature of things) and conclude that pluralist practice requires a meta-methodological construct to help navigate between the methodologies on offer.

Comparing and contrasting approaches to natural resource management, Kathleen Wilson and George Morren integrated the two meta-methodological frameworks described here, mapping hard, soft and critical inquiries onto an interpretation of David Kolb's experiential learning cycle. For example, for soft systems inquiry (practical action research), a cycle of inquiry was described in relation to the competencies of diverging (perceiving the problem situation, organization and issues), assimilating (developing logically consistent models with each community of practice), converging (testing models against situation) and accommodating (implementing within management systems).

Drawing upon the work of Wilson and Morren, Roger Attwater and Chris Derry have outlined a methodological cascade in relation to an example of environmental risk communication. A pluralist methodological toolkit is described, with action research focusing on risk perception, behaviour and opportunities for co-management and agricultural and ecological research and design. The conclusions drawn from this study included the role of action research in engaging issues at a number of complementary levels: processes to assist the identification and communication of co-constructed strategies within and between communities of practice, the use of experiential frameworks to assist as a structured meta-methodological guide, the role of these processes and frameworks as parts of larger systems of adaptive urban and landscape management and the practical outcomes emerging which can contribute as exemplars for similar complex issues of sustainability in different situations.

Another recent and engaging example is the work of Renata Phelps and Anne Graham in addressing the complementarities of action research and complexity theory. The application described is the important contemporary area of professional development in relation to information and communication technology. This mix of critical reflection on pedagogy, technology and complexity is an obviously fertile ground for issues of pluralism. The authors extend the impact of the shaping of research according to the epistemology and assumptions of the researcher to include the key aspect of the sociopolitical context of the inquiry.

METAPHOR

The German philosopher Friedrich Nietzsche famously called truth a 'mobile army of metaphors'. This statement speaks to the influence metaphor wields in human experience. Simply put, metaphor is thinking, speaking or writing about one thing in terms of another; however, this definition does little justice to the prevalence of metaphor in thought and communication. Deeper studies into linguistics, psychology and neuroscience have yielded similar conclusions that human beings naturally think in a metaphorical way. The brain's tendency towards categorization is substantially aided by metaphor as it instils both connectivity and distance among our thoughts. Not only do people discover similarities among concepts and objects by metaphoric linkages (often characterized as conceptual metaphor), but they also uncover wider flexibility within our world views as they metaphorically connect seemingly disparate concepts (typically labelled as linguistic metaphor). In this intricate relational process, metaphors serve as the symbolic currency within our discourse, generating considerable power in writing and reflection as well as serving as a catalyst for action.

Metaphor in Writing

As a mode of figurative language, metaphor is often connected with writing. Perhaps most commonly, analysis of metaphor is pervasive in literary fields where novels, plays and poems employing language rife with metaphor are subjected to intensive study. However, limiting metaphor to merely fictional or poetic realms neglects a wide variety of metaphorical usages. Ultimately, metaphor in writing serves as an encapsulation of the triangular relationship among the author, the reader and the text. In terms of the author, employing a metaphor is a compositional choice, one that reflects the author's style and intention. Moreover, the author also recognizes that the text does not exist within a vacuum, and thus, metaphorical choices will inform the reader's understanding of the sentence and text. Finally, metaphor is a gesture towards intertextuality, or the concept that texts interact and inform one another. As a writing convention, a stylistic choice or a means of reference to another text or concept, metaphor functions as a symbolic linkage to other writings, thus completing the reciprocal rapport between the three integral concepts of the compositional process.

Metaphor and Culture

While metaphor is most commonly situated in compositional environments, metaphor also has a powerful influence in several facets of society. True, the connection between the author and metaphor can prove deeply personal, yet in larger sociological and anthropological lenses, metaphor unveils itself as a cultural conception. Some metaphors, such as money as a means of exchange, hold near universality, but even in these instances, such metaphors hold differing cultural nuances. This is even more prevalent in metaphors unique to certain cultures. In a now canonical work of anthropology, Clifford Geertz wrote on what he perceived as the symbolic functionality of cockfighting for the Balinese, linking the practice to a number of cultural elements. Indeed, a culture's symbols and metaphors can speak volumes, helping in understanding that particular culture, yet at the same time, it is important to recognize that every metaphor is both an intensely interpretative and a highly dynamic act. Rarely static in its scope and varying richly from culture to culture, metaphors hold possibility for illumination and misinterpretation; therefore, researchers must work with metaphors carefully.

Metaphor and Action Research

The metaphors for action research are numerous and diverse. Action research has been compared with popular concepts like jazz music and esoteric ideas like

Giles Deleuze's rhizome. The wide variety of metaphorical applications within action research speaks of its complexity and fluidity. More so than any other methodology, action research possesses an undeniable multiplicity. Due to its participant-focused research agenda, every action research study is different, and the vast number of metaphors applicable to action research communicate this reality. Furthermore, scholars practising action research should investigate and explore metaphor in their writing since action research actively resists standardized formality. With every study, new metaphors expand the textual power of action research, further distancing it from the status quo. This is especially appropriate in arts-based action research, where research appropriates similar metaphoric elements found in literature to better describe and serve the needs of participants.

In performing action research, researchers should also possess awareness of the relevant metaphors to their participants. Largely, problem-based forms of action research, like Participatory Action Research, often engage with the basic metaphoric creation of problems and solutions. Once these metaphors are identified, researchers and participants can work together towards generating action. Additionally, given the participant-focused methodology, action researchers often work with the personal and cultural metaphors of participants, and the researcher must balance a variety of interpretive lenses from numerous stakeholders who have different understandings of the issue. Frequently, the participants in an action research study have a stronger grasp on the issues and the relevant metaphors than the researcher. This is particularly true when the researcher is working with participants of different cultures where metaphors and concepts hold multiple explicit and implicit meanings. Therefore, the researcher should take this opportunity to uncover, with the participants, the meaning of metaphors in order to better grasp the nature of the research situation.

More importantly, the interpretation of these personal and cultural metaphors is the result of the collaboration between the researcher and participants. For instance, Photovoice, an action research methodology in which participants take photographs of a particular problem, is a methodology that utilizes the power of collaborative metaphor. The photographs serve as emotionally charged metaphors for the participants' perspective on the issue, and the researcher engages the participants in a dialogue to unveil the meaning of the photographs. This example serves as but one model of metaphor's prevalence in action research. As a co-operative meaning-making methodology, action research resonates with a highly metaphorical character. In writing and practice, action research's approach is a plethora of metaphorical patterns, each holding a

unique place within the researcher's understanding of the issue. However, the most pivotal translation of metaphor for many action researchers is that translation of thought into action as researchers and participants mobilizes their constructed metaphors into realms of actuality, ushering true social change.

MICROPLANNING

Microplanning is a methodological innovation in the field of action research. Microplanning may be defined as a planning and implementing process which is people centred, relying on their decisions.

Some refer to it as 'bottom-up planning' because the planning starts from lower levels, unlike more traditional top-down planning processes. It is also known as 'participatory planning' as the community is involved at every stage of the planning. Sometimes, it is also referred to as 'local planning' as the unit of planning is a local predefined area.

The Need for Microplanning

The need for microplanning arose as central planning alienated local people from local assets and resources. In general, when people are alienated, they will use the services as long as they are available but will not invest time, labour or resources to maintain the system or services. To fill this gap, planning at the local level with the participation of people was tried out. The microplanning recognizes the need to involve people in the process of development through a microlevel planning process.

Focus of Microplanning

Microplanning can be used in the following circumstances, to name a few:

- To build the capacity of people
- To increase the information base of the area and its people
- To use available resources
- To identify the root causes when problem-solving
- To increase decision-making capacity
- To improve the socio-economic and legal environment of the predefined local area
- To enhance negotiation abilities of the community

The Process of Microplanning

The microplanning process empowers a community to arrive at their action agenda by engaging all stakeholders such as government functionaries, elected representatives or other key resource providers of the predefined local area. Microplanning processes essentially build the capacity of a community to analyze their own situation and to work on it. The duration and timing of each process differ as the common goal for each practising microplanning community is different.

The Phases of Microplanning

The three phases are pre-planning, planning and post-planning.

In the pre-planning phase, the central theme is to lay the foundation for the microplanning process. It begins by identifying the parameters of the area for which the community wants to find a solution. An orientation workshop or face-to-face meetings with key stakeholders are useful to clarify doubts, generate curiosity and build consensus.

The planning phase starts by collecting data from each of the smallest units of the identified area. This is followed by prioritizing of the problems of the area. The community analyze the data and strategies for resource mobilization and prepare the microplan, including the budget.

The post-planning phase consists of the implementation of the microplan and the review of the implementation from time to time.

Microplanning and Community Development

The three phases will help with community development. The phases organize the community and local key members to go through the stages of mapping resources in the area. Together, the community analyze the cause and effect of the problems and motivate all to think of workable solutions. They prepare the microplan and the budget together. The microplan is then

formalized and sanctioned by the appropriate authority or relevant departments.

Microplanning and Organizational Development

As success depends on participation by the local community at every stage, they have to be drawn into the processes of environment building, awareness generation, mapping, planning and implementing. The immediate objective is to change the present trend to locally available resource use towards greater sustainability and better equitable economic growth.

The community organizational efforts are more vital than mere technical inputs. Self-reliant voluntary efforts and the community's knowledge and experience enhance organizational development at the local level. To generate enthusiasm and self-reliance, some innovative local actions or projects like providing simple drains near water points, cleaning up the local area and installing a garbage disposal system may be initiated. These processes are more effective than lecturing and dialogues and consequently strengthen organizational efforts.

Microplanning and Action Research

Microplanning is closely related to action research. Firstly, generating awareness through inquiry forms the core of microplanning. Secondly, both aim to build the capacity of the community to analyze their own situation and work on it. The community members are treated with genuine deference and respect for their knowledge, experience and perceptions. Thirdly, both generate changes in the body of knowledge which lead to changed perceptions and boosted ability. Collective confidence forms the core of microplanning. It leads to the creation of a standing, trained volunteer force besides truly representative development committees and societies. In the long run, these systems provide excellent support to local elected bodies. Fourthly, the process ensures that the collaborative mode is adopted so that a problem is considered from all possible angles. This needs attitudinal changes too. The solution which arises out of it is acceptable to all stakeholders. Lastly, microplanning enables a community to arrive at their action agenda by engaging all stakeholders. Ensuring implementation of a microplan by the community completes the cycle of action research.

Thus, microplanning changes ordinary citizens into researchers who decide for themselves what kind of development they want.

MINDFUL INQUIRY

Mainstream science embraces the idea that the universe and human decision-making operate according to causal laws which can be objectively known. Understanding human behaviour requires an understanding of the mind. A great part of the workings of our mind, however, is based on subjective data, which is complex, detailed and often not replicable. Therefore, this view tends not to get a dominant place in mainstream science. The action research approach, however, leaves room for such subjective data. Mindful inquiry is a means of studying the mind. This entry focuses on the origin and the practice of mindful inquiry, an age-old technique that is recently being adapted for use in mainstream management. Mindful inquiry—as a means of understanding human behaviour and natural or social phenomena—has been applied by Western, Indian and Buddhist philosophers and saints. Mindful inquiry is a sort of foundational philosophy and easily adapts to different forms from intellectual first person inquiry, dialogues, reflexive individual thinking and contemplation to meditation. In this entry, mindful inquiry is discussed in the context of research. First, the mind is defined in its process of generating knowledge, then mindful inquiry is described and then an integral yogic view is proposed on knowledge and its impact on our attitude of inquiry followed by its application in the context of action research.

Mind and Knowledge

The mind gives us thought, observation, reasoning and cognition through separation and analysis of information. What the mind actually does is to process information about our lives and our environment. Psychological research has shown us that the thought process is prone to errors due to the mind's tendency towards preferences, desires and preconceived notions. These biases

stem from our senses. The mind sees things in parts and uses the process of reasoning and synthesis to put things in appropriate relation to each other. So the mind gives us partial knowledge. Sri Aurobindo (1872–1950) said that this process results in incomplete and inaccurate knowledge, which he terms *knowledge ignorance*. Because the mind cannot see the true wholeness or essence of that which it seeks to know, man developed an ego to help organize and develop effective capacities. This resulted in identifying with the ego and separating from the oneness or spiritual knowledge that is our highest truth and potential. Based on this perspective, Sri Aurobindo distinguished four different types of knowledge present in our outer mind.

Objective, Scientific Knowledge

Sri Aurobindo calls this *indirect knowledge* as it is mediated by our senses. He points out that this form of knowledge is inherently separate from a person's inner self because he or she experiences, here, a difference between the self as knower and the world as known. In this mode of knowing, individuals partly identify with the world but also dis-identify with it when they perceive the world as 'out there'. Ordinary science only recognizes this first type of knowledge. In the context of research, usually this is labelled as the third person approach. Information is gathered by listening to others, reading or conducting objective experiments and measurements. Usually, the affect of the person is not involved unless the topic of study is related to emotions. Mindful inquiry does not deal with this type of knowledge.

The Knowledge of Inner Processes

This covers emotions, moods, desires and thoughts. According to Sri Aurobindo, this knowledge is direct but *still separate*. In this mode of knowing, a person partly identifies with the mind and uses it to view another part of the mind. The cognitive process separates the knower from the known. This type of knowledge is thus based on experience; it becomes the person's knowledge; while it is internal and subjective, it can be talked about and shared. In research, we can ask about these experiences from a third person approach. Mindful inquiry can be applied to gain this type of knowledge, but it is not necessary. Self-reports through questionnaires can be adequate as well.

Knowledge of Inner Processes and Identification With Them

This occurs, for example, when individuals are completely consumed by a feeling such as happiness or anger and this feeling drives their action. This

mode of knowing is more or less preconscious and pre-reflective. In this type of knowledge, the person is directly involved in the experience. It refers to a state of realization. The thoughts, basic attitudes and perspective on reality are changed, but one's nature remains largely unchanged. This can happen through practice of mindfulness. It is experiential knowledge of inner processes, for example, if someone says, 'I am really happy' or 'God is so kind to me'. In this stage, the person is the thought. This is uncommon in research but can occur under the label of experiential knowledge and can be expressed in techniques such as participatory inquiry, mindful inquiry and action inquiry.

The Knowledge Where There Is No Separation Between Self and Knowledge

This type of knowledge has no foundation in the senses. But humans can train their inner instruments of knowledge to become as reliable and unambiguous as their outer senses. This stage is totally beyond the mind and can be labelled as pure consciousness. In the fourth type of knowledge, the whole nature of a person has undergone transformation. The first person approach of research is relevant in the second and third types of knowledge as they go beyond the mental mind, but they still can be traced through experiences. The second type can be approached by objective introspection of inner processes—by looking objectively at what is happening inside oneself. One can say, for example, 'My hands feel cold'. It is the person himself who is observing. The second (realization) and third (experience) types of knowledge can occur spontaneously or through lots of effort. They happen suddenly, and those who experience it can remember the exact date and time they occur. Transformation, the fourth type of knowledge, however, is a gradual process that comes as a result of gaining the other types of knowledge. It is not something that can be achieved through direct effort. The fourth stage is not accessible by means of 'mainstream scientific' research as it goes beyond the mind. Mindful inquiry often focuses on the second and third types of knowledge.

What Is Mindful Inquiry

Mindful inquiry can be defined as empowering the researcher both psychologically and philosophically by putting the researcher—rather than the research techniques—at the centre of the process. It is about awareness and observation through the inner processes of the researcher and the research subjects (second type of knowledge) and even about identifying with these processes (third type of knowledge). It originates from the Buddhist concept of mindfulness in combination

with phenomenology, critical theory and hermeneutics, leading to the following 13 assumptions:

1. Awareness of self and reality and their interaction is positive and present in the research processes.
2. Multiple perspectives are tolerated and integrated.
3. The deep layers of consciousness and unconsciousness underlying assumptions are considered.
4. The process of interpreting both self and others is ongoing.
5. All mindful inquiry involves accepting the bias of one's situation and context and trying to transcend it.
6. Mindful inquiry is immersed in and shaped by historical, social, economic, political and cultural structures and constraints.
7. Knowledge implies that researchers care for the world and the human life that they study.
8. Inquiry should eliminate suffering.
9. Existing values, social and personal illusions and harmful practices and institutions should be critiqued.
10. Mindful inquiry should contribute to the development of awareness and self-reflection in the inquirer and may contribute to the development of spirituality.
11. Mindful inquiry requires giving up ego.
12. Mindful inquiry may contribute to social action and be part of social action.
13. The development of awareness is not a purely intellectual or cognitive process but part of a person's total way of living her or his life.

These assumptions can be applied when studying several types of phenomena, such as understanding a culture and one's behaviour, communication and performance in the context of action research.

An Integral Yogic Attitude to Mindful Inquiry

Mindful inquiry focuses on the second and third types of knowledge. Are there approaches to reach out to the fourth type of knowledge or even to all four types of knowledge? Interestingly, we know—based on descriptions of spiritual paths—that we can grasp the meaning of the fourth type of knowledge by seeking the realm that is beyond the mind through techniques of silencing the mind, such as Vipassana, or by travelling to the ocean beyond the mind through using a meaningless sound, such as in transcendental meditation. It requires an integral yogic attitude to inquiry, which is

about understanding both the inner and the outer self where the researcher observes both himself and the research subjects.

Sri Aurobindo talks about an integral yogic approach to understanding all types of human behaviour by inquiring into the four types of knowledge. We borrow insights from integral yoga and formulate three principles:

1. *Aspiration*, a deep call to focus on the process rather than on the results (this requires an in-depth analysis and not a superficial observation of what a researcher thinks, feels and experiences when studying a phenomenon)
2. *Rejection*, or becoming aware of and withdrawing from all wrong habits and the false identification with the ego when giving meaning to observations and feelings
3. *Dedication* to the phenomena of study

These can be added to the research design where the researcher asks himself whether or not these principles are present and notes his findings prior to beginning the research. This can be done as a standard part each day or for each phase of the research.

Willis Harman developed such an integral approach in research. He referred to the inward-looking East and indigenous peoples and their intimate relationship with nature as examples of world views that can become part of the provisional epistemology while including the objectivist-positivist-reductionist epistemologies. Ken Wilber is also known for his integral theory of phenomenon, stating that everything can be studied by applying his four-quadrant model. This model focuses on two dimensions, first the I-We perspective and second, both the objective and the subjective perspectives, resulting in four quadrants.

Although he did not label his approach as integral, Harman gives a more detailed research approach where he incorporates both outer objectivity and inner subjectivity. The attributes of this alternative are as follows:

1. It should be radically empirical, which means that it will be phenomenological or experiential in a broad sense. This implies that it will include subjective experience as primary data and not only physical sense data. It includes the full range of human experience. For example, if consciousness is studied, then the study becomes an interaction of the observer and the observed or the experience of observing.
2. It takes objectivity and attempts at being free from hidden bias in dealing with data from external as well as internal experiences.

3. It insists on intersubjective validation of knowledge even if this can only be done incompletely, especially when dealing with deep, inner experiences.
4. It places emphasis upon the unity of all human experience (even religious experience). This provides a holistic view in which the parts are to be understood through the whole and not through the opposite reductionist reasoning.
5. It may deal with models and metaphors that not only seem to conflict with other models but which are also useful as they represent certain aspects of experienced reality.
6. It should recognize the partial nature of all scientific concepts of causality. This implies that making use of scientific laws can, in the end, also deal with causality.
7. It recognizes the role of personal characteristics of the observer and thus the processes and contents of the unconscious mind.
8. It is participatory, which means that it will not only deal with being detached, objective, analytical and coldly clinical but also co-operate with or identify with the observed and experience it subjectively.
9. It has a potential to transform observers, and therefore, it might lead to new criteria.

Mindful Inquiry in Action Research

Mindful inquiry can be applied in the context of action research with an integral yogic attitude of inquiry by focusing on both outer and inner perspectives of knowledge. The reflection phase of an action research cycle is often considered as a weak spot in action research. Mindful inquiry could be useful to action researchers by bringing a first person inquiry into the action research. First person action research, practice skills and methods address the ability of the researcher to foster an inquiring approach to his or her own life, to act with awareness and deliberate choice and to assess effects in the outside world while acting. It is believed that deeper levels of consciousness are a source of our actions (the fourth type of knowledge). Therefore, for understanding actions for analyzing a phenomenon and bringing change in perspectives of those involved, which is the core in action research, these deeper levels could be included in the research design by a mindful inquiry and integral yogic attitude of inquiry. What does it require in practice? The research designs such as those discussed above can be helpful but can also be an attitude of inquiry.

An attitude of inquiry from the outer perspective requires the following characteristics of the researcher

which can be found in first person approaches: curiosity, willingness to articulate and explore purposes, humility, paying attention to framing and its pliability, participation to generate high quality of knowing, developing capacities for working with multiple ways of knowing and engaging in and explicating research as an emergent process.

An attitude of inquiry from the inner perspective can be achieved through silencing the mind and listening to the voice within the heart. This means that during action research, such practices and exercises should be built in for the researcher to elicit from the four sources of knowledge, and if suitable, these can be integrated/implemented for all those involved in the research process. Future research on subjective knowledge in action research can benefit from this integral yogic attitude to inquiry and mindful inquiry approach.

MODE 1 AND MODE 2 KNOWLEDGE PRODUCTION

In 1994, Michael Gibbons, Camille Limoges, Helga Nowotny, Simon Scharzman, Peter Scott and Martin Trow introduced the terms *Mode 1* and *Mode 2* into the research literature, referring to Mode 2 as the 'new production of knowledge'. This entry describes the characteristics of Mode 1 and Mode 2 and relates Mode 2 to action research.

Mode 1

Mode 1 research is characterized by the explanatory knowledge that is generated in a disciplinary context. It is research that arises from the academic agenda, and that agenda usually takes place within a singular discipline and is accountable to that discipline. In many respects, Mode 1 captures the normal meaning of the term *science*. By this is meant that the aim of the research is to produce universal knowledge and to build and test theory within a disciplinary field. The type of knowledge acquired is universal covering law. The data is context-free and validated by logic, measurement and consistency of prediction and control. The role of the researcher is that of an observer, and relationship to the setting is detached and neutral.

Mode 2

In contrast to Mode 1, Mode 2 research has the following characteristics:

- It is produced in the *context of a particular application*. This means that it has a practical focus, perhaps a problem-solving one. It is relevant and useful to practitioners.
- It is characterized by *trans-disciplinarity*, in that it integrates different skills, multi- or interdisciplinary depending on the application.
- It is characterized by *heterogeneity and organizational diversity*, in that multidisciplinary teams may be temporary and that members come and go as the situation unfolds and as different skills are required at different stages of the project.
- It is characterized by *social accountability and reflexivity* where there is accountability to outcomes and to the participants. This involves reflexivity and a sensitivity to the process of the research itself and to, for example, the dynamics of trans-disciplinarity.
- It is characterized by a *diverse range of quality controls*, in that unlike Mode 1 where the question of knowledge production is judged from the stance of the discipline, Mode 2 draws on a broader range of interests, such as its application, and from the perspective of different stakeholders.

In short, Mode 2 is a completely different approach to research from Mode 1 (see Table 1).

Mode 2 challenges the established model of doctoral studies programmes in social science where typically isolated individuals engage in research within their field of expertise. In contrast, Mode 2 research is a network activity, and if applied to doctoral programmes,

<i>Mode 1</i>	<i>Mode 2</i>
Set by academic interests	Formed in context of application
Disciplinarity	Trans-disciplinarity
Homogeneity	Heterogeneity and organizational diversity
Hierarchical and preserves its form	Heterarchical and transient

Table 1 Contrast Between Mode 1 and Mode 2

it would involve teams of researchers working together with some form of collective assessment and examination possible.

Mode 2 Research and Action Research

There are rich parallels between Mode 2 and action research. Indeed, it is argued that action research has been engaging in Mode 2 research since the first action research experiments in the 1940s and 1950s. Table 2 illustrates how Mode 1, Mode 2 and action research may be juxtaposed. Mode 1 represents traditional organizational research, while Mode 2 and action research share features of trans-disciplinary collaboration, reflexivity and an orientation to co-generating actionable knowledge. Mode 2 and action research both produce knowledge in the context of application, that is, both seek to generate actionable knowledge. Both work in contextually embedded settings working with particular, situational data. Both work in an experiential and collaborative mode with the trans-disciplinarity that the situation demands. The researchers are actors and agents of change who are immersed in the setting and are, thereby, socially accountable to those with whom they work. Both engage in reflexivity as they pay attention to the process of action and reflection as they unfold.

MONDRAGÓN CO-OPERATIVES

The official name of this world famous co-operative group now is the Mondragón: Humanity at Work, and its extensive website details its structure and operations: <http://www.mondragon-corporation.com/ENG.aspx>. It is the most successful and largest labour-owned and labour-managed co-operative group in the world, currently employing nearly 84,000 worker-owners in over 200 co-operatives in Spain and in 18 other countries.

These co-operatives are a mould-breaking exemplar of participatory management within capitalist enterprises. Composed principally of member-owners who work at and co-manage their own co-operatives within the larger collective structure, they are membership organizations. All members join by paying the equivalent of a year's salary into an account to their co-operative. That account remains theirs and rises and falls according to the business results of their organization, thus giving them a direct stake in the organization's success. All members have a voice and vote in the management of their own co-operative and in the general assembly of the co-operative system as a whole. They are consulted about the annual business plan and vote on it, including the relative allocation of profits between investment in the future development of the co-operative and distribution in terms of salary. The co-operatives have a narrow salary range, the lowest

salaries being set at a level comparable to decent entry wages within the region and the highest salaries restricted to between 9 and 12 times the amount of the lowest salaries.

They are divided into a set of central service co-operatives including a health-care system, a retirement system, a co-operative bank and central financial and human resource services. They are further divided into sectors: consumer goods, industrial production goods, retailing, finance, research and development and education.

The co-operatives were founded in 1957 by a small group of students led and taught by a local Catholic priest, José María Arizmendiarreta. This took place in the depths of the isolation and recession that followed Franco's imposition of a fascist dictatorship on Spain and the systematic punishment the fascists inflicted on the Basque Country, among other regions of Spain that had tried to preserve the Republic.

Mondragón itself was a small industrial town almost completely abandoned by its upper middle and upper classes because of the amount of labour strife and social tension existing within it. There was little employment, and in the few factories that were operating, the working conditions and salaries were poor.

Arizmendiarreta had been given responsibility in the parish for youth education, and he gradually tutored a group of students up through completing a university engineering degree, a significant accomplishment since the public Basque universities had been closed by the fascists and the students had to go to take their university examinations in another region.

When this group of young men found that their engineering competence and the San Simonian principles of collaborative work could not be respected in the

existing workplaces in Mondragón, the priest helped them create the first manufacturing co-operative and, soon after, others, then a co-operative bank, health-care system and pension system. This effort grew quickly to become a major manufacturing force in Europe with an annual doubling and tripling of the workforce. Those without resources could combine education and work, working part of the day to finance their education during the rest of the day. The early education efforts resulted in the founding of co-operative schools and, much more recently, the founding of a co-operative university with four campuses and over 4,000 students.

The Mondragón co-operatives have an important link to action research. Not surprisingly, they have long been a focus of attention for those interested in one form or another of industrial democracy and co-operation, a key thread in action research, particularly in the industrial 'North'. Their combined social structure and immense economic success stand in stark contrast to the doctrines of competitive, Tayloristic capitalism based on worker exploitation and managerial privilege. Those organizations in which all members have a say, members' knowledge is valued and used and the distance between the top and bottom is managed in favour of those at the bottom are successful, which clearly means that such organizations are possible.

The well-known sociologist and professor of industrial and labour relations, William Foote Whyte and his wife, Kathleen King Whyte, visited the co-operatives while Arizmendiarrreta was still alive and then later determined to do a major book on the co-operatives. In the process of this work, they involved the author because of his anthropological research in the Basque Country that began in 1968.

Whyte, Greenwood and José Luis González Santos (then Director of Human Resources for the central service group of the co-operatives) acquired a grant to conduct collaborative research, and Greenwood and González ran a 3-year action research project on the co-operatives which trained about 45 co-operative members in action research processes. This project resulted in the alteration of some of the key processes in human resource management to bring them more into agreement with co-operative principles. It also resulted in two books co-authored with co-operative members, one in Spanish and one in English. The Spanish edition served as an orientation manual for new co-operative members for at least a decade after the work was done.

Some key action research lessons emerged from this work. The co-operatives and their ability to conduct action research processes leading to organizational change in democratic directions on an ongoing basis are not based on equality among the members but rather on the principle of solidarity and mutual support within a framework of acknowledged differences in skill,

gender, age and ethnicity. Another is the importance of their commitment to the ongoing perfectibility of the system through constant reassessment and change. The co-operatives view themselves as always at risk and always in need of improvement and development, a clear example of Mode 2 knowledge production in a world-class set of learning organizations.

There is an extensive literature on the co-operatives, most of which is cited in Whyte and Whyte (1991), and one particularly negative study of the co-operatives and their social impact by Sharryn Kasmir (1996).

MULTI-STAKEHOLDER DIALOGUE

Stakeholders are those people who have an interest in a particular decision, either as individuals or representatives of a group. This includes people who can influence decisions as well as those who become affected by the decisions.

The key objective of multi-stakeholder dialogue is to enhance levels of trust between the different actors, share information and institutional knowledge, create new knowledge and generate solutions and relevant good practices.

It is a flexible tool and can be adapted to a number of different contexts. It can be used at local, national, regional or international level. It can involve a small group of individuals representing different experiences and areas of expertise or can involve many different

stakeholder groups representing global constituencies and communities, such as trade unions, women, businesses, governments, youth and non-governmental organizations. Similarly, a multi-stakeholder dialogue can also be used to explore a given issue or topic as it can be used to directly affect the shape or content of a policy document or to discuss an implementation plan or strategy where each group puts forward desired outcomes and best practices.

Purpose

- A multi-stakeholder dialogue is a process to build a shared understanding on a particular issue, create a common platform among different stakeholders through dialogue, discussion and debate and initiate joint action planning.
- It is used when issues cannot be addressed or resolved by a single set of actors but require co-operation between many different stakeholders or interest groups.
- It is often initiated to bring together various stakeholders with diverse agendas but with some underlying common interest.
- Multi-stakeholder dialogue helps analysis of a particular issue or situation and comes up with new knowledge; thus, newly emerged knowledge helps increase ownership and agreement for new actions.
- More often, it leads to common and agreed-upon actions to be conducted. However, joint action does not imply doing the same thing together; it involves assuming respective roles by different stakeholders for enhancing the overall purpose.
- This interaction and sharing of ideas and perspectives leads to a process of decision-making or finding out solutions or having direction emerge that is broad based and finds support amongst important actors whose interests are strongly affected by the issue.
- Multi-stakeholder dialogue is based on principles of promoting mutual accountability and equity in communication amongst stakeholders.
- This method is of great importance in the arena of development because most development problems demand multifaceted and multilayered solutions that involve a range of actors and stakeholders.

Pre-Requisites

Multi-stakeholder dialogue is not a tool for all kinds of problems or situations. It is possible only where there is a common concern, where dialogue amongst the

different stakeholders is possible and/or where listening, reconciling interests or joint solution strategies seem appropriate and within reach. Only under certain circumstances can multi-stakeholder dialogue be used for conflict resolution.

The organization or individual convening the multi-stakeholder dialogue should have credibility in the eyes of other stakeholders. Therefore, the selection of the convener can greatly ensure or influence the outcome of a multi-stakeholder dialogue.

Steps for Organizing Multi-Stakeholder Dialogues

Select Theme(s)

The issues to be addressed—those which require active deliberation by the different stakeholders—will determine which theme is selected. Clear themes, questions and topics for discussion need to be formulated depending on the desired outcome, the relevance to stakeholders and the context of specific needs.

Select Stakeholders

The next step is to identify the key stakeholders from the large array of institutions and individuals that could potentially affect or be affected by the issues. Two factors that need to be considered are influence and importance. Influence refers to the degree of power which stakeholders have to set the direction of the decisions to be made during or after the dialogue process. Importance relates to the degree to which the issue demands the active involvement of a given stakeholder group.

Select Place and Material

Selection of place must be such that it is convenient for all stakeholders to reach. Neutrality of the venue is also another concern as the use of certain premises might be viewed as taking the side of a particular stakeholder. Hence, the choice of premises is of significant importance to ensure equitable participation of all relevant stakeholders.

Relevant material, such as reports, studies or handouts, which simplify the process and make it easy to understand, should be collected or developed to provide a starting point for discussion.

Conduct Pre-Dialogue Consultations

Pre-dialogue consultations help outline the subject up for discussion, clarify the organizer's expectations from participants and define clear terms of engagement. It also helps to avoid any kind of misunderstanding, and it helps focus the dialogue and prevents side topics diverting attention from the main issue.

These consultations also help create awareness and interest in a new theme that can subsequently be taken up for action by some of the participants in the long term. Pre-dialogue consultations with individual stakeholders also reduce the gap of understanding and ensure that all participants have information up to a certain level.

Consultative meetings must be conducted with all stakeholders prior to the actual dialogue; it helps all stakeholders achieve their objectives and facilitates better dialogue.

Design the Event

The structure of the dialogue needs to be planned out in as much detail as possible. Besides following the above steps for preparation and having all logistic requirements in place, it should include details such as the following:

- Structure and flow of the multi-stakeholder dialogue
- Role of various participants
- Length of the multi-stakeholder dialogue
- Process to be followed during dialogue
- Contents
- Materials to be used
- Deciding the convener and her or his role

Implement

Implementation refers to the actual multi-stakeholder dialogue event. In general, the multi-stakeholder dialogue process involves a four-stage process: (1) inputs, (2) group discussion, (3) plenary and (4) discussion of plan of action. The length of a multi-stakeholder dialogue can range from 2–3 hours (involving high-level government officials) to 1–2 days (especially if the community is involved), depending on the purpose of the multi-stakeholder dialogue, number of participants, levels of multi-stakeholder dialogue and so on.

Input Session

The input session is the opening session where the background to the theme and its current relevance are presented. Input sessions usually involve presentations of study findings, cases, surveys and data on the theme and create a backdrop for the event to follow.

It is also appropriate to lay down ground rules for the dialogue at this stage. Seating arrangements during the actual multi-stakeholder dialogue have the ability to influence the direction of the dialogue and reinforce existing power equations. Therefore, it is important to consciously plan the seating arrangements.

Group Discussion

Once the stage is set, it is time to elicit participants' views on the subject through a discussion. Group discussions are used to identify issues and come up with action points for the future.

During this session, participants' knowledge level, perspectives and comfort level in discussing the issue with other stakeholders must be taken into consideration when dividing participants into groups.

Plenary Session

During the plenary session, the outputs from various small group discussions are consolidated and presented in a large group. The plenary can either consist of representatives from all the groups or a combination of such representatives and resource persons or experts who can provide further inputs or suggestions for further action. The facilitator plays a crucial role in consolidating the inputs so that a fair picture is presented and suggestions can be taken up in the future.

Discussion of Plan of Action

As part of the plenary, a plan of action is prepared, roles and responsibilities of different stakeholders are worked out and decisions are taken regarding how to proceed in the future.

This session plan can be altered and modified depending on the nature and objective of a particular multi-stakeholder dialogue.

Write Up the Report

It is always effective to allocate the responsibility of documenting the proceedings in detail to a specific documenter. The documenter should take the sole responsibility of recording all the deliberations and processes, which could be consolidated in consultation with the facilitator. Such documentation forms a guide for future initiatives that may result from the dialogue. Further, the report must be shared with all the participants.

Role of the Facilitator

The facilitator of the dialogue plays a key role during the event; therefore, it is important to have a person with sufficient experience and familiarity with the theme and a broad development vision to facilitate the event. The facilitator must be acceptable to the different stakeholders and their varying perspectives. Excellent facilitation and management skills along with the ability to manage conflict are other key characteristics that are required of the facilitator.

In fact, it is useful to plan the dialogue design in conjunction with the convener. It is also the facilitator's

responsibility to monitor the direction of the dialogue and make necessary changes in the process along the way to correct the process.

Challenges in Multi-Stakeholder Dialogue

- Selection of themes of a common interest and ensuring participation of all stakeholders
- Selection of participants with non-bias
- Effective pre-dialogue consultation and preparation by participants who will be involved in the dialogue
- Dialogue design (some participants can be reluctant to speak up in certain circumstances)
- Capacity of facilitator
- Effective documentation

- Effective follow-up of dialogue output and its use
- Garnering resources

N

NARRATIVE

Narrative is a broad term describing the form of discourse generally known as a story. It may be presented in a number of different ways—through writing and its various forms, such as fiction, autobiography, and poetry; visually, through photographs, paintings or film, using images to document or represent events, or orally, through storytelling, conversation, interview and drama. All narratives tell of experiences and are commonly constructed to highlight a particular aspect or event, offering a powerful means of acknowledging and remembering them. This entry first outlines the key features and history of narrative and then focuses on approaches to narrative within research. The entry ends by summarizing and emphasizing the links between narrative and action research.

A feature of narrative is that it conventionally contains a beginning, a middle and an end and develops through its telling. As the story unfolds, characters, or players, are introduced, and often a character takes on the role of the narrator in a first person story. The unfolding might also take the form of a third person account or dialogue, as in a dramatic presentation or interview. Temporality is central to narrative, as a means of allowing the unfolding sequence of events and of organizing experiences within a time frame.

Aristotle's *Poetics* is considered one of the earliest writings to have defined the narrative plot, though Walter Ong's discourse on orality demonstrates the widespread use of non-linear narratives in oral cultures for transmission of information before written cultures developed. Religious texts such as the Sutras, Qur'an, Torah, Bhagavad Gita and Bible, having their basis in early oral narratives, all use recognized narrative structures to transmit philosophical, humanistic and behavioural guidance.

Narratives can be derived from personal (individual or collective), institutional, cultural or social sources and allow the narrator the capacity for extension and

for change. Such changes might come about through framing the story over a longer period, during which further events develop that change the story's conclusion, or through psychoanalytic intervention, where individuals might seek to perceive themselves differently or to elicit behavioural changes that might change their personal story or their perception of it.

Narratives are often framed within a broader meta-narrative or grand narrative which serves as a defining theory into which the local or personal narrative may not fit. Since society itself is storied and, when presented historically or reflectively, frequently biased in favour of those in positions of power, areas of friction emerge between the meta-narrative and the individual narrative. This allows counter-narratives and new social and cultural knowledges and acceptabilities to be produced. Thus, a narrative is also created through the agency of the cultural actors or storytellers who make known these 'new' stories.

Action research uses narratives through actively listening to stories of personal experience. This process can affect both the direction of the research and the narratives of other participants within the dynamic, emergent quality of effective action research. As narratives emerge organically, individuals express their own experiences and understandings to give access to deeper and richer knowing than is commonly available in more conventional research modes. The participants or co-researchers gain an awareness of how their ideas have developed, their reactions to specific events and the ways in which they might be dealt with differently. When that process is repeated throughout the participant group, and as the stories gather detail and input from others, additional interpretations emerge to give multi-vocal and multilayered insights to issues.

Approaches to Narratives in Research

Narrative research is the term given to a form of qualitative research that produces rich, detailed and descriptive

results. It comprises a number of methods that can be used singularly or in combination with each other. The use of narratives in research expands the capacity of any work to develop an in-depth understanding of a problem, and for this reason, it lends itself for use in conjunction with other research methods.

Narrative can be used with other qualitative methods such as focus groups, case studies or surveys to gather richer, denser material. Alongside quantitative studies, it can illuminate research findings, for example, by adding resonance and memorability to statistical data.

Narrative Inquiry

As with other forms of inquiry, narrative inquiry centres on a research question or issue to be investigated. It differs from other forms of research in that rather than seeking to clarify a specific and static question from which the inquiry may start, the inquiry constantly changes shape as the research progresses. D. Jean Clandinin and F. Michael Connelly describe this as a process of searching and re-searching, of continual reformulation of the problem as compared with the problem definition and solution focus of conventional research.

Narrative inquiry uses the experiences of participants or co-researchers to explore a problem and may include the initiating researcher's own experiences. The inclusion of such autobiographical details and individual responses to the problem acknowledges the presence of the researcher and, arguably, demonstrates the researcher's real engagement with the research issue.

A narrative approach necessitates negotiation skills in managing the evolution of the research problem and the relationships between researchers and co-researchers. As the research proceeds and information gathering takes place (usually in the form of notes or recordings), it is transformed into a research product using an analysis of the narrative. A frequent marker of narrative research is a referral back to all those involved in the production of the research and inclusion of their responses as integral sections of the research text. The purpose of this might be to acknowledge the different voices and validate responses to the production or to deliberately mix the researcher and the participant voices in the production of a 'messy text'.

Narrative Analysis

The analysis of a narrative research will be determined by the context and values contextualizing the research problem: Political, feminist, post-colonial, economic, therapeutic or other frameworks might provide that context.

Any narrative might be also analyzed by its structure using the methods developed by Vladimir Propp,

who classified Russian folk tales into five themes with 31 elements (narratemes) that he considered applicable to all tales.

This structuralist analysis was further developed by William Labov, a sociolinguist who defined six elements of narrative as essential to making an experience (or controlling idea) 'tellable' and worth being heard. These were (1) an abstract (short summary), (2) orientation (time, place and characters involved that often direct the reader/listener's leaning towards the situation and characters), (3) a complicating action (a series of events that affect the story development and provide its plot), (4) evaluation (narrator commentary to indicate the significance of the story), (5) resolution (the final action and second part of the plot that solves the complicating action) and (6) the coda (the satisfactory ending of the story that offers a sense of completion).

A simplification of this is known as Freytag's Pyramid (originally developed by Gustav Freytag in 1863 as a means of explaining dramatic action). The pyramid structure serves to illustrate where action in a story is built up, as in the steep side of a pyramid, reaches a climatic event and then proceeds to decrease tension, as on the opposite side of the pyramid, until it reaches a conclusion and resolution.

The psychologist Jerome Bruner (along with Paul Ricoeur) argues that narrative is the only means of describing 'lived time'. Bruner takes a functional approach to narrative analysis by asking how the stories serve a purpose in individuals' lives and how they assist in making sense of life events and their potential for transformation.

Others, such as Norman Denzin and Ken Plummer, take their narratives from, and analyze them through, an experiential lens against the social, political and cultural context. This kind of analysis produces a dense, subjective reading that can give rise to counter-narratives and a representation of marginalized individual or group experiences.

Analyzing a narrative in this way offers a means of understanding how the story has been constructed rather than the content of the story. It becomes possible to understand the social positioning in which the narrator places himself or herself, what is important in the narrator's view, who the main perpetrators were and how they affected the outcome of the story. It also offers a perspective from which to re-examine the wider social, political or cultural backdrop against which it is framed.

Collective Narrative

Collective narrative, including collective biography, gives a complexity to the process of gathering narrative, its facilitation and analysis. The aim is to produce

a multi-voiced, multilayered narrative account. This begins with skilled facilitation which invites each participant to contribute input and establishes an emotionally safe environment in which that might take place. Drawing on Frigga Haug's memory work, a project arising out of the apparent disparity between female experience and prevailing political ideologies, Bronwyn Davies and Suzanne Gannon offer a framework upon which to perform the practice known as collective biography.

The knowledge from collective narratives gathered in this way is necessarily diverse and thus problematic in serving as a resolution to a research question. Its strength instead lies in the sense of agency participant or narrators gain through having their stories heard, the reflective questioning of narrators about their stories (as opposed to opinion gathering) and the production of complex, embodied, insightful research. That these might be then re-examined and used reflexively supports the practice of action research with its emphasis on redefining and extending research boundaries.

Issues Associated With Narrative

Issues that confront narrative research frequently centre on the ethics of the relationship between the initiating researcher and the co-researcher or the participant. The degree of familiarity and involvement might change throughout the process and may be an expected, possibly desired, effect of such research. That this is acknowledged and included in the research product is paramount in demonstrating authenticity of account. Narrative practitioners regard these windows to complex human interactions, including failed attempts and mistakes, as marks of validity in narrative research.

Objectivity is seen as desirable in conventional research based upon the view that there is an objective reality that is unaffected by researchers, participants or its social, cultural or political milieu. Narrative research refutes this, arguing instead for impartiality as the vital factor, with personal interest and involvement in the research issue indicative of engagement and commitment to the work.

Ownership too presents questions in narrative work. In a situation where co-researching takes place and where the details of participants' lives are presented in detail, in their own words, questions of ownership can arise. The work of both Patti Lather and Chris Smithies and that of Donna West take the opportunity to include these frictions as part of the narrative, adding to its impact as a co-production.

The aspiration for narrative work is to move beyond the current recognition of the value it adds to more conventional accounts in an economy-driven research environment to a wider acknowledgement of its significance in its own right. While narratives contribute a degree

of complexity and subtlety to any investigation, its emancipatory, transformative potential need also to be acknowledged. Social benefits in the form of therapeutic encounters, group support, community development or civil action might emerge during the course of narrative inquiry. It is precisely at these junctures that action research approaches combine with narrative in virtuous cycles: The transformative, action-oriented ambitions of action research are supported and enhanced by narratives; and at the same time, the practical and social developments made possible through an action orientation add further wealth and depth to the original narratives. The value of narrative lies in this reflexive action that becomes the driver for positive and effective research outcomes.

NARRATIVE INQUIRY

Stories are ubiquitous. Narrative thinking pervades almost every aspect of human culture, communication and discourse and has the potential to be the great

discovery for the human sciences. Narrative is fundamental to the social and cultural processes that organize and structure human behaviour and experience. Its relevance to action research is that narrative, as a primary mode of human knowing, offers an apparently effortless way for the mind to intrinsically code human action. If we view action research as involving the production of practical knowledge useful to people in their everyday lives, then narrative inquiry can be seen as a focus on how people are already doing this for themselves.

The study of narrative is a broad, multidisciplinary field, ranging across philosophy, literary theory, poetics, cinema, cognitive narratology, anthropology, sociology, organizational studies, psychology, psychotherapy, education and even medicine. Such a wide field leads inevitably to a range of methods of study, and this entry must, of necessity, limit its focus to narrative research that is concerned largely with the collection and analysis of personal narratives and the social, cultural and organizational contexts in which these arise. Some important pioneers associated with such an approach include Vladimir Propp, Paul Ricoeur, Jerome Bruner, Donald Polkinghorne, Elliot Mishler, Barbara Czarniawska, Catherine Riessman and Arthur Frank.

Listening for Peoples' Stories

Narrative inquiry involves listening (or looking) for peoples' stories. Whether this is in casual or formal conversation; in a group meeting or in a focus group; in a structured, semi-structured or 'narrative' interview; in biographical research or drawn from diaries, letters or other kinds of documentation, it seems clear that people are constantly immersed in narrative. Narrative is a portal to human thinking. People use stories to explain their own and others' past actions, provide a commentary on current activities and anticipate the possibilities of future events. Stories are imaginative and *world making*, bringing order and meaning to everyday experience and can be unsettling and disrupting as well. Stories need to be told. People tell their stories to reveal their feelings and concerns, to make a point, to entertain, to fulfil social demands, to fit in with what is expected and/or to challenge the status quo. In stories, people become engaged in creating a sense of identity both in the stories that they choose to tell as well as in the way they tell these stories. Frank has suggested, 'The capacity of stories is to allow us humans to be'.

Narrative Thinking

Narrative inquiry is much more than simply collecting stories. To appreciate its full scope, it is necessary to

appreciate that people are not merely telling stories but are actively participating in narrative thinking to make sense of their world. This narrative thinking organizes material events and human actions into sequential structures coded spatially and temporally, and at the same time, it adds colour, perspective and emphasis that effectively code human concern. The spoken and written narratives that stem from this thinking provide an efficient basis for the sharing of human knowledge and experience, as well as for establishing human self-identity. The philosopher Paul Ricoeur has remarked that in a society where narrative has died, its people would no longer be able to exchange their experiences.

One crucial feature of narrative thinking is that it has its own type of *logic*. The American philosopher Charles Peirce (pronounced 'Purse') has proposed a third mode of logical inference, which he calls *abduction*, running alongside deductive and inductive inference. Peirce's idea is that there is a mode of everyday thinking and human meaning making that works along the following lines. An unexpected or unpredicted event is first observed. But if it is hypothesized that *if* a certain notion is true, *then* this event could be regarded as a matter of course, then there are grounds to believe that this notion can explain the observed event. This kind of reasoning, which has come to be known as *inference to the best explanation*, fits precisely with how narrative thinking seems to work. What is most striking is the ease with which people seem to use a *narrative circumspection* in making sense of their experiences. People, when confronted with something that requires being made sense of, quickly and efficiently seize upon a story that puts the event into a plausible context. People are unwitting natural 'abductors'.

Narrative-Oriented Inquiry

Narrative inquiry, as opposed to the general study of narrative, does not entail simply following a basic set of steps or rules. It is better approached by carefully designing a specific narrative project, then considering appropriate ways of collecting the data, followed by making choices in analyzing the data. To this end, a dynamic framework for good practice, called Narrative-Oriented Inquiry (NOI), has been outlined by David Hiles and Ivo Čermák. The NOI model emphasizes transparency, inclusivity and a distinctive, pluralistic, critical approach to data analysis. An adapted version of this NOI model is presented in Figure 1.

NOI stresses the importance of starting the design process with *research questions*, formulated in the light of the focus of the study and the participants involved. Then, with the research question in mind, an *interview guide* is set up, outlining possible topics for an unstructured interview. A *narrative interview* follows

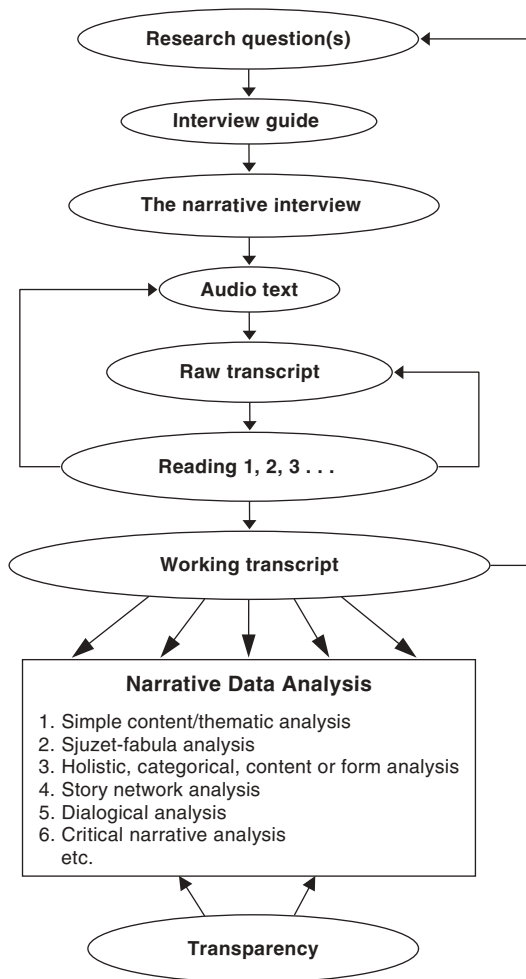

Figure 1 A Generalized Model of Narrative Inquiry

SOURCE: Adapted from Hiles, D. R., & Čermák, I. (2007). Narrative psychology. In C. Willig & W. Stainton-Rogers (Eds.), *SAGE handbook of qualitative research in psychology* (pp. 147–164). London, England: Sage.

the recommendations of Mishler, who sees such an interview as necessarily involving a joint construction of meaning. This interview normally requires digital audio recording to generate an *audio text*, which will be closely transcribed using transcription software. Of course, as an alternative to the audio text, written responses or other documents may be used. In whatever way the data is collected, the aim is to produce a *raw transcript* for the data analysis to begin.

This transcript is then read through several times (*Reading 1, 2, 3 . . .*) to build up a picture of the story as a whole. Some preliminary coding can then be employed. The only rule that needs to be followed at this stage is that the transcript should not be tidied up. Narratives are basically a sequence of episodes, or

events, and it is useful to produce a *working transcript* that uses a numbered sequence of self-contained episodes, or *moves*, in the telling of the story. Indeed, any transparent separation into specific units of analysis determined by the data-analytic strategy being planned might be used.

Choosing Approaches to Narrative Data Analysis

The final feature of the NOI model is the choosing of one or more approaches to narrative data analysis. Six strategies are considered here, but many more are possible. The important consideration is that, in choosing any analytic strategy, the research question is kept foremost in mind.

Simple Content or Thematic Analysis

This is the most basic approach to narrative analysis, covering a range of possibilities. These have been widely used in the field of qualitative inquiry, but in themselves, they are superficial and are not able to do justice to the narrative form being studied. It is generally accepted that it is a fallacy that a story can be reduced merely to a set of themes. Nevertheless, depending upon the original research question, this basic approach can sometimes be useful.

Sjuzet-Fabula Analysis

This approach to analysis provides the groundwork for further narrative analysis to be taken up. It involves breaking down the text into its two basic, underlying and interrelated components: into *sjuzet* (i.e. how the story is being told) and *fabula* (i.e. the sequence of events being related in the story). The fabula, if it is read through, ignoring the *sjuzet*, reads as a coherent but rather dull story. By contrast, it is the *sjuzet* that provides drama, emphasis, commentary, reflections as well as the subtle codes of the situated, occasioned action of the telling of the story.

Holistic, Categorical, Content or Form Analysis

Amia Lieblich, Rivka Tuval-Mashiach and Tamar Zilber have proposed an approach that uses four basic perspectives to analyzing narrative. Its strength is that it is probably more comprehensive than some other approaches and provides a broader context within which the two approaches above can be placed.

Story Network Analysis

David Boje has focused upon a range of analytical tools for organizational narrative research. His approach focuses on the *social architecture* within

which stories reside and circulate and how these stories are dynamic, assembling and disassembling as self-organizing systems. Towards this end, he offers a visual way of story mapping that is designed to code this complexity.

Dialogical Analysis

Frank has developed a socio-narratological approach to the study of narrative. In line with the basic premise of NOI, he advocates a view of 'method' as a heuristic rather than a prescriptive guide. Narrative analysis is by necessity dialogical, but Frank, in his approach, stresses how in the interpretation of stories there is a need to respect the underlying layers of imagination and realism that are reflected in the storyteller's struggle in a search for meaning.

Critical Narrative Analysis

An explicitly critical approach to narrative analysis is best exemplified in the work of Peter Emerson and Stephen Frosh. They characterize their approach as psychosocial, embracing the critical approaches of discourse analysis combined with sensitivity to individuals' active construction of meaning in their lives. It is possible to extend their work by considering the importance of undertaking a microanalysis of both *sjuzet* and *fabula*. Indeed, it is usually found that the subtleties of the *sjuzet* are especially important in understanding the ways in which individuals make and remake their *identity positioning* with respect to the story they are telling. These identity positions seem to point to an underlying fundamental narrative intelligence at work, active in the contestation between identity positions versus subject positions, and in the taking account of social and institutional contexts, power issues, the discursive context and so on. Throughout any critical analysis, interpretation is sustained by the continual refrain 'Why is this story told this way?'

Further Issues in Narrative Research

Finally, it is worth stressing that using the general approach to analyzing narrative data that is outlined here is something that can turn out to be surprisingly satisfying. The experience is that with the hard task of transcription over, one might first stare at the text slightly bewildered, wondering how to make sense of it. Then, using one or more of the approaches covered here, everything begins to fall into place. Gradually, insight into the core themes of the narrative, the active construction of meaning and the subtleties of the telling become clearer, and deeper critical issues begin to emerge.

Narrative inquiry also raises a critical ethical issue. Narratives can be highly personal, and research

participants may be easily identified from their stories. Extreme care needs to be taken in action research, especially where an 'institutional' context is involved, with respect to anonymity and confidentiality.

David R. Hiles and Ivo Čermák

NEW PRODUCT DEVELOPMENT

The practice of product development is focused on the development of new engineered, manufactured products. Here, reducing both the product development interval and production cost while increasing product functionality and sustainability is a critical concern of managers. This concern is not unfounded. The rate of introduction and success of new products rely on the way in which managers structure, run, evaluate and improve their product development practice. Lateness to market can lead to major loss of market share and of income, while pre-production problems, unresolved due to time pressure, can lead to high costs, product recalls and liability claims. What is to be managed includes the product development process, the organizational interfaces (both within and outside the firm), the incorporation of functional perspectives such as industrial design and design for manufacture and the evaluation of the performance. In looking to improve

practice and performance, managers investigate the practice of product development and examine how to (re)gain competitive advantage through improvements arising from

- learning from success and failure and
- developing and maintaining a fit between the firm strategy and product development task environment and a fit within the task environment between the development task, individuals and the formal and informal management systems.

Perspectives on Product Development Practice

Three related but different perspectives on product development practice may be taken:

1. Product development as a linear conversion process
2. Product development as a recursive system
3. Product development as a complex adaptive system (CAS)

Product Development as a Linear Conversion Process

The first perspective sees product development as a (relatively) simple transformation process, converting inputs to outputs. The inputs are in two forms: (1) *transformed resources* and (2) *transforming resources*. The transforming resources (e.g. staff and design equipment) act on transformed resources (technical, market and time information) to convert an idea into a finished product, ready for release into the market. For example, the task of converting ideas into specifications, prototypes and finished products requires the flow of people, information and materials. The information and materials may be held in storage in raw or semi-processed states as the process evolves.

This perspective on product development as a linear conversion process is based upon relatively fixed, discrete and sequential stages where the flows and outcomes are relatively deterministic. It provides a simple and effective representation of the structural logic and flows associated with a stable product development situation. However, it leaves undeveloped the dynamic behaviours and relationships associated with the notion of product development as a process of discovery and translation into tangible and marketable outputs.

Product Development as a Recursive System

The second perspective sees product development as a process with concurrent and multiple feedback

loops that generate iterative behaviour and outcomes that are more difficult to predict. This process encompasses the activities, decisions and responses required to take a product from concept to market. The core process consists of five areas: (1) product development, (2) teamwork and organization, (3) process development, (4) market focus and (5) transfer to manufacturing. Leadership, resourcing and the use of appropriate systems and tools enable the core process of product development. A successful product development process leads to improved development performance, which is evaluated in relation to goals set for product launch and measured in terms of both product performance and customer satisfaction.

From this perspective, product development is a dynamic and fluid process, and radical innovations are possible. However, even though the perspective allows for two-way flows of communication, it does not allow explicitly for structural or behavioural instabilities in the process as the development activity proceeds.

Product Development as a CAS

The third perspective sees product development as a CAS. From this perspective, product development is non-linear, self-organizing and emergent. The feedback loops in the process produce sensitivity and potentially disproportionate outcomes seen in terms such as development time, product quality, product cost, manufacturing dependability or manufacturing flexibility. The process as a whole self-organizes, independently adapting and developing new configurations. Correspondingly, emergence occurs because the process allows experimentation, rule breaking and exploratory actions. The benefits of such a perspective are that it assumes that overall process configurations and behaviours are malleable.

Action Research in New Product Development: The Strategic Opportunity

The dynamic nature of product development practice, especially as viewed from a CAS perspective, underpins the usefulness and usability of action research as a means of enquiring into, learning from and improving practice. The practice of new product development is amenable to the application of action research to enable a process-based and learning mechanism-based approach to organizational transformation. Such transformation is especially relevant for organizations faced with developing new capabilities to address emerging market and technology-based demands and opportunities. However, in this respect, the practice of new product development is similar to that in many other areas of managerial responsibility.

It is in the development and application of platform thinking and product family planning that there is a specific opportunity, particular to product development. From this strategic perspective, individual products are based upon product platforms which encompass the design and components shared by a set of products, enhanced over time and from experience. In turn, product families and their related platforms represent the application of the firm's core and emerging capabilities. So a disciplined approach to developing and extending product families forms a strategic basis for achieving short-time intervals in the development of new products. A firm may use a core capability assessment to improve a product family. Such core capabilities are inherently dynamic and vulnerable to lack of patience, failure to adopt innovations, breaking up design teams and coasting on success.

Summary and Conclusion

At its core, product development is about problem-solving and decision-making under conditions of market and technological uncertainty. The choices open to managers challenge their capabilities to anticipate and to react to new information or experience. A strategic focus carries with it a requirement for discipline in understanding and improving practice, together with the various contributors from different functions.

NIELSEN, KURT AAGAARD

Kurt Aagaard Nielsen (1948–2012) was born and spent his childhood in northern Jutland in Denmark, where he grew up on a small farm as the youngest of four children. As a young man, he went to Copenhagen in order to study sociology at the university, and at an early age, he became a professor in the Department of Sociology. In the nineties, the department was shut down and reorganized—due to a critique of being too leftist in its academic production and too radical in its experiments with new forms of democratic decision-making as initiated by former students from the students' movement in the seventies, among them Nielsen. He went to Roskilde University (at the time Roskilde University Center) as a professor, with working life as his primary field of study, and here, his work with action research was developed. He was an inspiring and beloved teacher and supervisor, characterized by a 'social orientation' in his personal conduct that corresponded with his theoretical position and the spirit characteristic of his action research. Privately, in his younger days, he lived in different communes and later on in a nuclear family. He had four children, all boys, and at the time of his death, he lived with his second wife and his two youngest sons. He died from cancer in 2012 at the age of 63.

Intellectual Horizon

Nielsen's intellectual orientations were shaped in the late sixties and seventies through his participation in the students' movement as part of the 'new left'. He became one of the central figures in developing a sociological self-critique, questioning the established (and mostly undebated) ways of thinking and doing sociology, which in the Danish context at the time were strongly positivistic. The critical students wanted to reflect and question sociology in its societal relations and functions and in its historical-epistemological logics as well. Different forms of rereading of Karl Marx here played a crucial role. Among these different readings of Marx, a structural reading inspired by Louis Althusser was highly influential, but Nielsen instead turned to the tradition from critical theory (Max Horkheimer and Theodor Adorno) based, in the

first place, on the German sociologist and philosopher Oskar Negt and Alexander Kluge's book *Public Sphere and Experience*, published in 1972. This is a tradition that is not well known to a primarily English reading public; to have an impression of this way of theoretical approach, therefore, one might look to a work such as Moishe Postone's 1993 book *Time, Labor, and Social Domination: A Reinterpretation of Marx's Critical Theory*, which could be said to take a similar stance to Negt's.

Negt in his writings focused on modern work seen in a societal and subjective, experience-based perspective, and he especially elaborated the constellation of 'work and human dignity' as a concrete utopian horizon within which all analyses of modern work should be elaborated. Nielsen grasped this thematic analysis, and in his doctoral thesis, he developed his theory of a (potential) *social orientation* as something inherent to modern work. Later on, he connected this critical theoretical way of analysis to a pragmatist approach as developed by Richard Sennett. In its empirical dimensions, this core area of his academic work was elaborated in close relation to his work with action research that took form through the 1980s and onwards, which also transcended the pure critical stance of his early work. The problematic nature of modern work thus remained a central interest of his, but his action research had a larger span.

Critical Utopian Action Research

From the mid eighties until his death, Nielsen co-created a specific kind of action research which eventually was called Critical Utopian Action Research, primarily together with Birger Steen Nielsen, but especially in the first, initial period, they both also worked closely together with Peter Olsén and Kirsten Paaby. (Nielsen and Olsén also became professors at Roskilde University, while Paaby went to Oslo, Norway, where she was the co-founder of the independent institution *Idebanken* [The Bank of Ideas].) They brought various disciplines and traditions together, such as sociology, social psychology, psychoanalysis, philosophy, social learning theory, people's enlightenment, drama and critical theory, and setting out from this constellation, they developed Critical Utopian Action Research.

The inspiration from Negt's ideas of experiential learning and efforts trying to build up 'counter public areas' was important, and so was his idea of democracy as a way of living, which could easily be combined with a more general inspiration from the work of Paulo Freire. Studying the work of Kurt Lewin, with its basic democratic tenor, led to the conceptualization of these aspirations as a kind of action research. But the strongest

impulse came from the Austrian German publicist and grass-roots activist Robert Jungk and his idea of Future-Creating Workshops.

Practically developed through a series of major action research projects, they formed Critical Utopian Action Research. It was conceptualized and practised as committed to the democratization of societal life in all its common dimensions. Compared with many other forms of action research as they are practised today (especially in the different forms of fusion with managerial strategies), this basic and radical democratic commitment could be said to mark a specific profile of Critical Utopian Action Research. Today, it is still primarily based in Denmark, but with ramifications for Norway and Sweden as well, and its influence is growing internationally.

The democratic endeavour is intimately related to putting a critical dimension at a central place in action research, but inextricably, it is bound to a utopian dimension—as the two poles of a relation—giving the practical, experimental work its direction and dynamics. Experience shows that this kind of action research furthers the emergence of social imagination understood as a transformation of the participating citizens' everyday life experiences. And social imagination, for its part, could be understood as pivotal to action research that seeks to further citizens' courage and ability to develop and take over responsibility for their 'common affairs'. This takes place not in isolated autonomy within bounded communities or interest groups but in broader co-operations within different kinds of public spheres and, thus, also transcends everyday life experiences, among other things, by getting into mutual dialogues with experts of different kinds. Thus, Critical Utopian Action Research still adheres to a classical action dimension interpreted in a basic political sense as related to autonomy and emancipation. This could be said to mark a difference with broad tendencies in today's participatory research, most obvious perhaps in Interactive Research, explicitly leaving the *action* term behind.

Thus, Critical Utopian Action Research tries to emphasize a societal dimension as crucial if you want to be true to the legacy of the work of Lewin and Freire while at the same time emphasizing the necessity for a strict localization of the concrete action research projects, staying close to people's everyday life. In line with this, it also seeks answers to the current crisis (understood as an erosion of sustainability, welfare and democracy), which includes problematizing modernization agendas as such with their instrumental and strategic, but nevertheless illusory, proposals of solutions. As an alternative to this, the concept of commons has increasingly been put at the centre of Critical Utopian Action Research.

This horizon also implies a rejection of the notion of purely local knowledge in favour of an idea of the general or the universal dimension within the local or particular. This has impacts for the interpretation of the research dimension of action research that is linked to this dialectical unity of local and universal or particular and general, and therefore, the role of the researchers also widely transcends the dimension of being a facilitator. This also marks a distance to the paradigm of Mode 2, with its strictly pragmatic idea of so-called robust, local or contextual knowledge as the criterion of relevance and of the quality of knowledge creation.

Major action research projects in which Kurt Aagaard Nielsen played a decisive part concerned (a) the transformation of urban everyday life, working together with unemployed, mostly younger citizens from Copenhagen along with his colleagues Paaby and Nielsen; (b) the democratization of industrial work, working together with unskilled female workers within the Danish fishing industry ('Industry and Happiness') and with Olsén and Nielsen; (c) the development of alternatives to volatile, fluid and limitless relations in work, working together with bus drivers and caretakers and with colleagues Lise Drewes Nielsen, Eva Munk Madsen, Katrine Hartmann-Petersen and Susan Mahler, and (d) two major projects on democratic nature management and local community development, based at two different rural locations in Denmark, working together with local citizens and with Nielsen. His publications on action research include a long list of books and articles, most of them in Danish and a few in English (and German) too.

Action Research as a Reflexive and Co-Operative Community

In the last decade of his life, Nielsen dedicated part of his work to building up connections between different parts of the relatively weak and dispersed action research community in Denmark and Scandinavia in the first place and also at an international scale. Thus, he was co-initiator in establishing a Danish Action Research Network, holding regular conferences, and he made significant efforts to bring Scandinavian action research milieus into dialogical relations. Likewise, he was co-initiator of the international network Action Research Action Learning Interest Group, arranging yearly Ph.D. seminars with participants from all over the world, and of the Center for Action Research and Democratic Societal Development at Roskilde University. Together with Lennart Svensson, he edited the volume *Action Research and Interactive Research: Beyond Practice and Theory*, which presents a broad picture of Scandinavian action research. Together with Ewa Gunnarsson and Nielsen, he was

working on a new book on Scandinavian Action Research, *Action Research for Democracy*, which is now being released with Gunnarsson, Nielsen and Hans Peter Hansen as editors. He was part of the editors' board of the journal *Action Research*. In the last text to be published by him alone, recalling the legacy from Wilhelm von Humboldt, he advocated the necessity of establishing action research as a critical, reflexive and co-operative academic community open and transparent to society in order to protect and preserve action research in its unique quality as a societally committed, free science. His own efforts within action research, indeed, might very well be regarded and valued in this perspective.

NOFFKE, SUSAN

Susan (Sue) Noffke often reminded people that her hometown of Appleton, Wisconsin, was also the home of the infamous Senator Joe McCarthy, the disgraceful ‘anti-communist’ pursuer of independent thinkers and activists. With her father, a unionist, working in the local mill, Sue’s frame of reference was always shaped by the need to resist the thugery of institutionalized violence and the imbalance of power it represented. As a middle school teacher (1972–82) in the Tomah and Monona public schools in Wisconsin, she was an active unionist (as well as local softball player) and took on the task of union bargaining, building her understanding of both her sister and brother teachers and district education politics.

From school teaching, Noffke went into academic work. In this world, Noffke is best known for her focus on educational action research: writing, teaching, doctoral supervision and projects with teachers and communities. From the mid eighties to June 2013, she worked in university settings, part-time as a teaching assistant in the teacher education programme of the University of Wisconsin–Madison while she worked towards her doctoral degree, then at the State University of New York at Buffalo (1989–93) in their teacher education programme and from 1993 to 2013 at the University of Illinois, Urbana-Champaign. A key focus for her teacher education work was in social studies teaching, which she was able to use as a platform for facilitating student teachers’ work in urban schools and their communities and working with local district teachers on social studies curriculum over a number of years. She had a lifelong passion for children’s books, using them to raise explorations of social and economic injustice through attention to social issues covered in her collection of books (now donated to the Urbana Free Library). Anti-racist education was a particular focus for thinking, reading, teaching and action on schooling, teacher education, social studies and curriculum theory; action research was a vehicle for following that concern through in multiple projects—with students, teachers, parents and communities.

Often, only those directly involved knew of such projects, although some reached formal publication in journals. She wrote with teachers to critique the cultural bias of standardized tests, lobbied with teachers whose children had to put up with blocked sewers at their school and helped organize the essay competitions which encouraged elementary students to write about (in)justice in their daily lives for Martin Luther King Day. Nine years of dialogue, co-research and

hard work in a school district showed up in classroom materials in schools and materials for teaching social studies in teacher education. The long-term social studies curriculum themes chosen by these local teachers reflect their concern for students as knowledge makers, alongside their teacher-researchers: historical thinking, problem-solving, citizenship and social justice. Such service to teachers and their students was a hallmark of Noffke’s commitment to teachers: helping to support them to become critical practitioners through curriculum development, working with communities and engaging in action research projects on current issues. There are many more untold tales of such commitment.

Working in a university thus gave Noffke an important base for her informed activism, working with local school districts and their communities as well as her classes, both undergraduate and graduate. She loved working with colleagues, including former students, building a large network across the globe, from Korea to Colombia, Mexico to Seattle, Liverpool to Cambridge and Cape Town to Melbourne. Her graduate class in action research was a place for local teachers and international scholars to find one another and their own projects. These students were welcomed into her family home regularly. She loved teachers and teaching—a job that was, in her view, a site for intellectual and daily practical challenges. It is this focus on teachers and their work that underpinned her interest in action research that makes a difference in terms of human dignity and justice.

Noffke wrote about educational action research using a framework that insisted on the links between personal, professional and political domains—not as separate domains but as necessary dimensions of knowing and acting. Her 1990 doctorate thesis considered action research historically, treating its emergence as a ‘family’ of related movements in the USA, UK, Australia and Germany. Here, she unpacked the labelling of different kinds of action research, being interested in the complex understandings that could arise from her historical studies and seeing the problems of calling one country or period ‘traditional’ or ‘technical’, another practical and yet another ‘critical’. In her view, such labels obscured the relationships between the different forms of action research and the inherent contradictions that each approach embodied, such as the tension between democracy and the social engineering impulses of USA’s efforts in the mid twentieth century. While she had her own preferences, she was not interested in pursuing the ‘definition wars’ of whose version of action research was more accurate, more empowering or more ‘pure’. Rather, she wanted to understand better how the local was connected to the broader social context,

history and power relations, in order to help change the present.

Noffke's major literature overview of educational action research, in the prestigious *Review of Research in Education*, started by reference to Martin Luther King's 1966 challenge to social scientists, namely, 'We ask you to make society's problems your laboratory. We ask you to translate your data into direction—direction for action'. Invoking this work, Noffke argued for action research as contributing to knowledge making for and by the teaching profession, in the service of justice, by making the argument that there are always links between forms of action research and politics and showing the personal and professional dimensions alongside those political dimensions. She argued that personal transformation is necessary but insufficient in action research for social change: The political is always in operation and can only artificially be separated from the personal or professional. To deny this political aspect is to support the agenda of the status quo, whether consciously or not. By pointing to the different purposes and benefits of different kinds of action research, Noffke gave signposts to help her readers unpack what is at stake in those differences and provided resources to address the tensions she saw as productive and generative in action research efforts.

In revisiting this argument in her chapter in the *Handbook of Educational Action Research* she co-edited with Bridget Somekh, Noffke pointed out how the stakes for educational change have altered around the globe, making action research both more necessary and more difficult in the policy climate that favours narrow forms of accountability, high stakes testing and research as measurement. Connecting the necessarily local activity of action research with global contexts and issues, she drew on the work of Arjun Appadurai, who argues for the right to research. For Noffke, this right meant commitment to action research that linked knowledge and practice, encouraging knowledge production among those usually marginalized from it, with personal, professional and political benefits in both knowledge and practice, redressing injustice.

Noffke died before her next book on action research for practitioners could come to fruition and while her projects were still under way. Educational action researchers will miss her tough mind and generous collaborations.

NON-INDIGENOUS ALLY

According to Ann Bishop, allies are people who recognize the unearned privilege they receive from society's patterns of injustice and take responsibility for changing these patterns. Becoming an ally means learning about systems of oppression, figuring out our own (conscious or unconscious) roles in maintaining those systems and then working alongside those most affected to try and address the inequity.

The concept of 'allyship' is a work in progress: Its research roots can be traced to a variety of communities, including the lesbian, gay, transgendered, bisexual, queer and two-spirited communities and their efforts to create safer and more meaningful engagement with researchers who desired to work with them. Much of the continued effort to understand authentic, genuine and honest 'allyship' has emerged from within indigenous and non-indigenous partnerships in community-based research. This entry examines the roles non-indigenous allies can play within action research environments by exploring the concepts of 'allyship', positionality and reflexive practice in relation to working with indigenous communities.

Each community may have a different and evolving definition of what it means to be an ally, but generally, the concept is imbued with the notion of cultivating, building and strengthening relationships between two differing individuals, groups or communities based on respectful, meaningful and beneficial interactions. Often underlying these alliances is a common goal to achieve some sort of collaborative change.

The context of research with indigenous communities globally is often rooted in traumatic experiences of research *on* rather than *in partnership with* indigenous

peoples. Indigenous communities experienced—and, in some cases, continue to experience—‘helicopter-style’ research where researchers enter communities, take the knowledge that they feel they need and then leave, with very little or no follow-up. A cycle of injustice and hurt has developed over time. In response, many indigenous communities have demanded models of better practice in research. These models relate not just to researchers who approach communities from a different racial or cultural background but also to those who may share cultural roots but enter a community with some piece of their identity or history positioning them as an ‘outsider’. This outsider experience may reflect being away from their community for years, being of a different socio-economic status than the majority of the community members, lacking the ability to speak the language of the community or various other differing characteristics.

Many of the best practice models that have been developed focus on the need for researchers themselves to engage with their own assumptions, beliefs and experiences prior to and during their work within a community. Linda Tuhiwai Smith, a well-respected author on the topic of research with indigenous communities, argues that the central teaching for non-indigenous researchers working with indigenous communities ought to focus on humility as a foundation for research. She encourages researchers to ask themselves, ‘What can I do? Can I actually do anything?’. She asks researchers to critically think through what it means to do research ‘in a good way’ with indigenous communities.

Many indigenous and non-indigenous researchers are thinking through the process of how to be involved in community-based action research in a way that respects the communities they are working within. Some non-indigenous researchers have described their experiences working with indigenous communities as journeys which challenge them to examine their own assumptions about indigenous peoples and about research more broadly. In addition to ‘unlearning’ assumptions about research, it is also imperative to learn about one’s own position within the many communities with which one lives, works and plays. A good place to start is by learning about one’s own cultural and family histories. Knowing about oneself and where one comes from creates a stronger ability to be honest with oneself about privilege and power and the ways these interact to create systems of oppression.

Positionality

Positionality can be defined as a self-understanding of the historical and contemporary identities each researcher brings into research relationships. In Peggy McIntosh’s famous article ‘White Privilege: Unpacking

the Invisible Knapsack’, she writes about how racial markers often afford some groups particular privileges that they may not even be consciously aware of (e.g. the privilege to go about daily activities free of racial discrimination or sexism). Her work has been drawn on by many indigenous and non-indigenous academics and activists who have challenged researchers to think about their positionality and ‘identity backpacks’. These metaphorical invisible (but sometimes very visible) backpacks, and their many compartments, need to be unpacked and examined in order to explore how they may affect our ability to engage in mutually respectful and humbling research.

Some non-indigenous researchers, who have been raised and educated within a societal system that has benefitted from and promoted colonization, may feel that their own positionality as non-indigenous people places them within the realm of ‘cultural outsiders’. Their recognition of both the historical and the contemporary aspects of their own identities—and how those identities relate to the violence and suffering of the communities they work within—is a key example of their own efforts to unpack their identity backpacks.

When working with indigenous communities (and other communities that experience structural oppression), it is common for students and researchers to find themselves questioning what can actually be done to be of service to the communities in which they work. This questioning can lead to a line of challenging personal inquiry around acknowledging and accepting personal limitations as researchers and as human beings. Some researchers learn to refer to this feeling as being humble(d). In *Decolonizing Methodologies*, Smith contends that embracing humility—through humour, self-reflection and experience—is a central component of finding mutually respectful spaces between indigenous and non-indigenous researchers.

For some students and researchers, defining one’s own positionality can be a challenging process. While a Western world view often privileges individualism, an indigenous world view sees everyone as interconnected with others in their social and natural worlds. As a result, knowing who we are, and where we come from, becomes a central part of formal introductions. Unpacking an identity backpack can help new researchers better articulate their history, and intentions, and can open the door for more fruitful and honest collaborations.

Exploring many parts of one’s own history and identity, including family history, cultural and sexual identity and past personal experiences, can be rewarding. For some, the journey of identity discovery is prompted through conversations with community members, research colleagues or fellow students. At their best, these conversations emphasize, in a gentle way, what pieces of one’s own identity puzzle may be missing or

yet to be discovered. These conversations may emphasize that it is crucial to know where one comes from and why one may be drawn to working as an ally with indigenous (or other) communities. Having this knowledge not only grounds us in the past but also allows us to walk a better path in the present and future.

Research, Practice and Reflexivity: A Proposed Model for Self-Engagement

Smith encourages researchers who are interested in decolonizing the research process (allies as well as indigenous researchers) to ask themselves a series of probing questions: Whose research is it? Who owns it? Who will benefit from this research? How will the results be shared and disseminated? Whose voices will be heard through the research? In thinking through (and negotiating) answers to these questions, researchers may need to engage in lengthy and fruitful discussions with their potential partners and come to a consensus about the ways in which a project will be approached and implemented. Developing a shared understanding of the purpose, goals and outcomes of the research, as well as how researchers intend to be/live within the community, can lay the solid foundations for a strong partnership.

Becoming an ally means learning to listen and engaging with these questions or conversations with humility and respect. It may mean becoming comfortable with uncomfortable moments and having assumptions and intentions challenged over and over again. Becoming an ally means being willing to make mistakes and to reflect deeply on those experiences. It means becoming conscious of what we don't know and taking the time and energy to pause, listen and learn.

Central to beginning this process is the notion of reflexivity. Reflexivity can be defined as making time to dialogue with one's self and with others. It is crucial to creating authentic and honest relationships between indigenous and non-indigenous researchers, and therefore to 'allyship'. The constant and evolving questioning of one's own assumptions and experiences challenges us to acknowledge and perhaps attempt to 'unlearn' those assumptions and experiences. In addition, it encourages discovery of one's own positionality through internal and external conversations. This process humbles; it asks for a critical examination of identity and place within the communities that students and researchers serve.

Model: The Relationship Between Research&Practice and Reflexivity

For some, it is helpful to imagine what a visual representation and reminder of this process may look like.

Figure 1 Visual Representation of Research&Practice and Reflexivity

One possibility of such a representation is a continuous double helix, with research&practice on one side and reflexivity on the other (Figure 1).

Because research and practice are so closely intertwined, particularly within action research, they are depicted here as 'research&practice'. The reflexivity side of the model represents continuous dialogue, whether it is dialogue with one's self, with others or both. In order to promote action research that aims to be genuine, respectful and humble in its actions, both sides need each other to exist. As can be seen in the model, the two sides of the helix balance each other; one cannot move forward without the other.

The arrows imply that the process relies upon constantly moving and evolving relationships. The need for this interconnectedness is even more pronounced when working as an outsider within a particular community or culture. Respectful research practice cannot take place between non-indigenous researchers and Aboriginal communities without a constant emphasis on critical self-reflexivity in terms of beliefs, values and positionality. It is imperative that this reflexivity is grounded in the continuous development of knowledge relating to the historical and contemporary experiences of the communities one is working within.

As part of unlearning one's own assumptions and embracing being humble(d), it is critical to also acknowledge that there are many aspects of the community in which one works that remain off limits in terms of access or understanding because of the position one may take as an outsider based on one's own identity.

Conclusion

The concept of 'allyship' is ever evolving. Indigenous communities are expanding the agenda of allyship

through concepts such as cultural safety and through policies such as ownership, control, access and possession, developed by and for First Nations communities within Canada. The roots of allyship are grounded in cultivating partnerships based on respect and humility. In order to attempt cultivating such partnerships, it is important to engage one's self in a constant practice of reflexivity and positionality: Where do you come from? Why do you do the things you do? What are your motivations? What are you gaining? Where is your heart at? Is your soul clear?

power and steering automatically improve on the conditions for participation?

By the 1950s, a growing body of research suggested that there was a need for a reasonable degree of freedom, or autonomy, in the work role for individual participation to be possible. Even more important was the recognition that making the notion of autonomy real created a need for active, constructive efforts, performed jointly by all concerned, and that this kind of constructivism did not follow automatically from any of the competing world views. Economic liberalism as well as socialism seemed to be associated with a continuously growing degree of division of work. This was the terrain entered by the Industrial Democracy Program in Norway when it appeared in the 1960s.

Initiated by researchers from the Tavistock Institute in the UK in association with the forerunners of the Work Research Institute in Norway, the programme implied generating new forms of workplace development processes that could halt the trend towards increased division of work and replace it with a trend towards increased autonomy for all employees. Even though the programme was developed in co-operation with the Confederation of Trade Unions and the corresponding employer association, it could not reach all workplaces even in a small country in one sweeping move. The initial focus was, consequently, on a limited number of field sites that could be provided with intensive research support. The expectation was that these projects could function as nodes in networks for diffusion throughout the working life.

The role undertaken by research in the projects drew inspiration from Kurt Lewin and his idea of action research. In advance of the projects, research had developed perspectives on the notion of autonomy and on the conditions needed for autonomy in work to become possible. Being run, although with modifications, as experiments, research was in charge of most of the organizational tasks emerging within the context of the projects, such as the establishment of steering and project groups and the initiation of meetings, conferences and other encounters.

The projects were successful and attracted much interest, even internationally. Most widely recognized was a project in a process plant belonging to the major industrial group in Norway, Hydro, where the pattern of hierarchically structured departments for the running of the factory, the control room and maintenance was replaced by shift groups where each group was responsible for all functions. This demanded new forms of integration between the operators and new mechanisms for deciding who was to do what at each and every time. Management was reoriented towards boundary conditions, experience-supporting training systems were introduced and salary systems were

NORWEGIAN INDUSTRIAL DEMOCRACY MOVEMENT

Along with the process of industrialization, there emerged debates about the effects of this process on democracy. Initially being structured around the two major world views—(1) economic liberalism and (2) Marxist-inspired socialism—the early debates came to centre on ownership, worker representation in the steering bodies of companies, the relationships between employers and unions and other similar issues. Stepwise, however, the issue of the participation of the individual worker entered the scene as well. Would new patterns of

changed from performance premium to competence premium. Productivity as well as quality was high, and the plant could be run by much fewer people than originally planned.

With this, the benefits of autonomy in work had been subject to a powerful demonstration. This notwithstanding, the experiments created discussion rather than a broad wave of concrete change. It is possible to see this as 'resistance to change', but it is also possible to see it in the light of the complexity involved in creating the kind of local constructivism needed to establish and sustain autonomy-based work. Ultimately, it is not only principles of job design that are at stake but also issues like labour-management relations in general, the role of experience in competence development, the extent to which society-level reforms support worker participation and local solutions and more. Instead of a direct replication of the patterns of the experimental projects, the situation in Norway became characterized by a development of the constructivist capacity of society, involving issues such as the co-operation between the labour market parties, the emphasis on participation in workplace health and safety, the establishment of more permanent systems for support to local development processes and the merger of workplace development with the development of networks, clusters and 'learning regions'.

Since the challenge of breaking the drift towards more and more division of work was universal, the Norwegian programme acted as a trigger for initiatives in many parts of the world. Specific projects resembling the Norwegian ones emerged in a number of countries, such as Sweden, Denmark, Germany, Holland, Canada and the USA, but there appeared many other initiatives as well, such as in education and training.

As far as research is concerned, there were, in particular, three lines emanating from the early projects: first, a continued development of the socio-technical systems perspective to provide a better foundation for the generation of autonomy and participation under variable technological conditions; second, a line of research providing a continuous examination of measures and methods in workplace development, in particular the turn towards more horizontal, or participative, relationships between research and its project partners, as reflected in notions like participative design and various forms of conferences reflecting the principle of equality between all participants, and, third, a line that came to focus on the constructive capacity of society's institutions, focusing on the role of the labour market parties, the characteristics of public reforms and other similar issues. Although these lines overlap, they also came to constitute somewhat different traditions as far as research is concerned.

The Industrial Democracy Program appeared at a time when the shadows from early industrialization, with great social distance between workers and managers, and associated class-based struggles and conflicts, were still strongly present. Today, autonomy and participation are mostly discussed purely with reference to issues like learning, innovation and the knowledge economy. The events that have occurred in several countries in the wake of the recent crises demonstrate, however, that learning, knowledge and innovation are not enough. There is a need for innovations to be socially responsible and for learning and knowledge to benefit all members of society and not only small groups of investors and owners. Although nobody would argue a return to the industrial democracy debates of the previous century, there is clearly a need to reintroduce the issue of broad participation as a challenge on the level of society.

NURSING

Nursing is the largest profession in the health-care sector. Modern-day nursing takes place in a range of settings and draws from diverse disciplines and foundations, including the health sciences, social sciences, humanities and human sciences, to inform its practice. In lay language, the term *nurse* is used to denote different but related practitioners, such as registered nurses, nursing assistants, nurses' aides and licensed practical nurses. The focus of this entry is on registered nurses (RNs). RNs have distinct scopes of practice and often oversee the work of the preceding health service providers. Furthermore, nursing developments that have taken place in the West have informed this entry. It is acknowledged that nursing has been in existence across

the globe and throughout history, and with the advent of technology and the professionalization of nursing, the differences in education and research approaches are diminishing.

History

Nursing has a long history of existence. Promoting healing among the ill and caring for the sick and dying were roles taken on by relatives, hired labour, religious sectors and volunteers across time and place. With the roots of modern-day nursing dating to Florence Nightingale's seminal and methodological approach to practice and research during the nineteenth century, the twentieth century saw the professionalization and *scientification* of nursing. Current-day nursing practice takes place within and across settings such as, but not limited to, communities, hospitals, primary health care, mental health care, public health, schools and policy sectors.

Education

Nursing education has seen rapid changes over the course of the past century. Specifically, with the expansion of the scientific paradigm across health disciplines, in the late nineteenth to the early twentieth centuries, nursing knowledge acquisition moved from informal to semiformal training, which often took place in hospitals and religiously affiliated hospitals. Beginning in the mid twentieth century, the education of nurses was further formalized as colleges and universities developed and offered programmes in nursing education. Currently, to become an RN, a minimum of 3 years of college education is required. In some countries, such as Canada, entry to practice requires a minimum of a university-based baccalaureate degree (except in the province of Quebec). Graduate nursing education has extended, with universities offering masters-level, and in some cases doctoral-level, nursing degrees. To enter academic positions, prior postdoctoral training is increasingly becoming a requirement. Higher levels of nursing education have had a reciprocal relationship with the rapidly growing research basis in nursing and recognition of the complexity of health promotion and health-care delivery.

Research

Current nursing research is influenced by scientific and naturalistic paradigms. As a result, nurse researchers can have expertise in quantitative, qualitative or mixed-methods approaches. Ontologic and axiologic differences are overtly recognized as nursing students, beginning at the undergraduate level, are asked to reflect on the implications of paradigms on research

approaches and methods. Depending on the research topic and the particular epistemological orientation of the nursing researcher, nursing studies can address a range of health questions and are very different from each other. For example, randomized clinical trials can be utilized to examine the efficacy of nursing interventions. Qualitative research traditions (e.g. ethnography, phenomenology, Grounded Theory or discourse analysis) can be applied to examine the health-related experiences of individuals, families or communities. As nursing researchers are gaining recognition across disciplines, they are increasingly leading multidisciplinary teams of researchers inquiring into nursing or health-related phenomena.

Practice

Nursing practice is informed by, and in turn informs, nursing research and education. Earlier, theoretical focus was on the person, the health-care system and the social/physical environments. Later, systems-oriented perspectives also played a role, as did recognition of the fluid and interactive nature of relationships across systems. More recently, notions of power, privilege and emancipation were also considered. As a result, nursing is an evolving profession that embeds diverse perspectives and ways of knowing. Nursing education exposes students to basic sciences (e.g. anatomy, physiology, pharmacology), health sciences (e.g. clinical nursing practice) as well as social sciences (e.g. sociology of health and illness) and humanities (e.g. cultural aspects of nursing practice). To become an RN, following completion of undergraduate or college education, graduates must successfully pass licensing exams. To maintain one's status as an RN, the annual renewal of a state or provincial professional nursing college registration is required.

Nursing Identity: An Evolution

The nursing profession's identity has gone through transitions, as its leaders have advocated for and established it as a distinct, autonomous profession and disciplinary field. Nursing's struggle for identity has been related to a number of intersections, including its (a) historical origins, (b) distribution of power within the health-care sector and (c) gendered labour force. Each point is further considered below.

Historical Origins

The historical origins of nursing draw from across time and place. The modernization of nursing practice has been an ongoing process and is informed by its scholarly and empirical evolution. It has also been influenced by nursing knowledge accumulated over the

centuries. The emergence and proliferation of multiple nursing theories in the twentieth century were among the efforts to establish its modern identity. Continuing debates about what constitutes nursing knowledge and what its paradigmatic orientation is, or should be, are a reflection of its establishment as a scholarly field. For example, *Nursing Philosophy*, a peer-reviewed journal, provides a forum for inquiring into the nature of nursing. The rapidly growing body of evidence (knowledge)-based nursing has brought its discipline into the scholarly fields.

Distribution of Power

To this day, the distribution of professional power and decision-making within the health-care sector remains unequal. Within the hospital sector, nurses have the responsibility to carry out medical decisions but not the power to make them. Yet in certain other health sectors, nurses have had higher levels of autonomy, such as public health nursing, mental health nursing and maternal-child nursing.

Gendered Labour Force

Nursing continues to be a gendered profession, with a predominant proportion of its labour force consisting of women. While the predominance of women is recognized as a strength of nursing in the eyes of the public (with notions of caring often being linked to women), the persisting gendered inequalities across societies (e.g. gendered income disparities and concurrent child-rearing and eldercare) continue to affect nursing in sustaining a consistently educated labour force at the full-time practice level.

Action Research in Nursing

Action research (and related approaches) has a particular relevance for nursing because both aim to link theory, research and practice. A growing number of nursing studies are applying action research, participatory research and Participatory Action Research approaches to examining health disparities with marginalized populations or within nursing practice. To date, most of this research, and in particular those studies drawing upon participatory research and Participatory Action Research approaches, have taken place in community settings. For example, the Community-Based Participatory Research study by Foster, Chiang, Hillard, Hall, and Heath (2010) focused on perceptions of maternity care in the Dominican Republic. Judith Burgess and Mary Ellen Purkis (2010) engaged nurse practitioners in British Columbia (Canada) and examined the power and politics of collaboration in their role development. Through MacDonnell's (2007) case study of community

nurses, which applied a feminist bioethics framework, public health nurses in Ontario (Canada) developed a policy resolution for ethical sexual diversity nursing research. In other examples, nurse researchers have looked at health-related phenomenon in community settings, applying Participatory Action Research with immigrant populations, such as mental health promotion with newcomer female youth, with newcomer male and female youth and with immigrant women.

Summary

In summary, modern nursing has experienced significant advancements over the past century and established itself as a scholarly and disciplinary field. Although nursing draws from different disciplines and foundations, it articulates its phenomena of interest in a uniquely nursing ontological position. Specifically, in the practice of nursing, differences between constructivist and positivist paradigms are strategically reconciled, recognizing that good nursing practice is both an art and a science. The twenty-first century will see continued expansion of nursing research and education, and its practice delivery will continue to be influenced by the gendered disparities persistent across societies. Action research (and related approaches) will continue to have a particular relevance for nursing.

OBJECTIVITY

See Philosophy of Science

OFFICE OF COMMUNITY-BASED RESEARCH

The Office of Community-Based Research (OCBR), University of Victoria, British Columbia, was established in 2007 in response to the desire of students and academics to pursue a community-based approach to their research and by community and campus members wanting to form mutually supportive research partnerships which lead to action on societal issues. A scan of the university in 2005 found that the practice of community-based research was fairly widespread but that many felt that little support was available to those wishing to pursue a career that included community-based research. The scan was followed by a university-wide symposium to see what kinds of energy existed for networking at the university itself. When nearly 20 per cent of the entire academic staff showed up for the symposium, the senior university administration felt that it was time to find a way to better institutionalize the evolving interests. In 2006, the administration then supported a six-month-long consultation and planning process with international and national advisors, multi-sector community members, funders, First Nations and campus members. When it was launched in 2007, OCBR became the first university-wide and community-university co-governed entity of its kind in English-speaking Canada.

The OCBR has worked to build capacity for community-university research partnerships that could enhance the quality of life and the economic, environmental and social well-being of communities. Its

founding director, Dr Budd Hall, established a working motto necessitated by both the small size of the unit and its philosophy of collaboration: 'It will do nothing that someone else is already doing and it will do nothing on its own'. Importantly, the OCBR was designed in function and form to be a joint project of the community and the university. A steering committee was formed to govern the work, with the head of a region-serving community organization and the vice president of research appointed as co-chairs. This steering committee, along with an external advisory group of internationally renowned experts in community-university engagement, was weighted equally between community-based and academic champions of community-based research (CBR) and campus-community partnerships. The steering committee has been fully involved in strategic planning and evaluation, and as public representatives and spokespersons for this Canadian and global pilot. The OCBR situated itself as a regional and Canadian incubator and hub for other Canadian and global efforts such as CBR Canada and the GACER (Global Alliance for Community Engaged Research), the latter supporting the European campus-community engagement and research/science shop movement. The shared vision between OCBR and the other national and global entities has been increasing the accessibility, relevance and responsibility of higher education in the broader society and the world.

While acknowledging that CBR involves community groups but not necessarily the university, for the purposes of the OCBR, it was defined as a collaborative enterprise between academic and community members that seeks to democratize knowledge creation by validating multiple sources of knowledge and promoting the use of multiple methods of discovery and dissemination. The goal of CBR, adapted from Strand, Marullo, Cutforth, Stoecker, and Donohue's (2003) discussion of best practice for CBR, is social action (broadly defined) for the purpose of achieving (directly or indirectly) healthy and sustainable communities.

Indeed, as the work of the OCBR evolved in parallel with other initiatives at the university such as knowledge mobilization, service learning and civic engagement strategies, the terms *community engagement* and *community-engaged research* became more reflective of the work of the OCBR. Community-engaged research refers to scholarly activity that requires partnership development, co-operation and negotiation and commitment to addressing community issues. For the practices of the OCBR, it further meant supporting *mutually beneficial* community-university research partnerships.

The OCBR immediately attracted the interest and funding of academic and community foundations and granting, and donor bodies that wanted to access and develop new practices, partnerships and policies to create change and movement. They were interested in critical issues in the community where multi-sectoral collaboration on the community side had already emerged but multidisciplinary approaches on the academic side were needed. Housing affordability, community planning, indigenous language and culture revitalization and local food production were some of the key issues that were at the core of OCBR activity. Woven through the attention to critical issues for action were CBR capacity-building forums, including institutes, seminar series for teachers of CBR, work on criteria for merit review and promotion as well as involvement in building Canadian and global networks. OCBR grew very fast over the first 5 years, mainly due to its attractiveness as a concept-in-practice, and interestingly, much of the director's time included helping develop similar entities across Canada.

As John McKnight once observed, 'Institutions do not build community, citizens do.' OCBR endeavoured to remain as a 'space between' the desires and needs of both a societal institution and a constantly changing community and society. What has been widely acknowledged is that there is a creative but real tension between community and university interests and needs. In the consultation that led to the founding of OCBR in 2007, it was indigenous leaders who spoke most eloquently from their own experience of being affected negatively by research and educational institutions over the past 100+ years in Canada. In their work with the OCBR's steering committee and partnership projects, it is they who have had the greatest impact and the most compelling vision for a new way to work as responsible and responsive citizens in a democracy. Their struggles and stories have inspired the OCBR by recognizing that the world needs multiple knowledges and respectful partnerships between multitudes of knowledge holders in order to strive for a vision of a better world.

In 2013, building on the success of the OCBR, the University of Victoria made a further commitment to community engagement and community-engaged research. As part of the establishment of new structures to enhance the university's capacity in this regard, the OCBR was reimagined into two new units, a support services unit and a scholarly research and practice centre. The Research Partnerships and Knowledge Mobilization unit offers a suite of practical services in support of community-university research partnerships and knowledge mobilization. The Institute for Studies and Innovation in Community-University Engagement provides a space for the study and practice of engaged scholarship. It is a *reflective* space to enable, learn from, theorize and support community engagement practices and is an *enabling* space for community-university research. Focused on engagement, the institute harvests new knowledge that will contribute to solutions of community issues, public policy development and improved theory and practice.

ONLINE ACTION RESEARCH

Online action research is research that is initiated, conducted and concluded *online* through the use of the Internet and web-based technology. Action research serves as both the vehicle for change and a method of analysis of change through an interactive inquiry process that engages individuals in solving problems through thoughtful actions and research. Traditionally,

this cyclical process happens through collaboration and in a community where participants are connected in a tangible way. Lack of face-to-face interactions and relationships built upon physical and real-time social contact may be considered barriers to Participatory Action Research (PAR) from a traditional action research perspective. However, online action research offers opportunities to expand how action researchers conceptualize PAR communities and research.

The idea of conducting action research *virtually* is an emergent practice. The Internet and the tools used with the Internet, such as the World Wide Web and e-mail, expand the boundaries of communities to outside their villages, towns, cities, states, provinces, countries and even global hemispheres. As more connections between people are made possible by the Internet, individuals and communities are challenged to reassess their concept of 'Who is part of my community?' and 'Where is my community?' This increased availability of connections to people, governments, educational institutions, community groups and more through an online connection fosters the evolution of the method of engaging in action research. Online action research offers potential for expanding action research collaboration, planning for action, data collection, reflection and analysis to communities connected through their shared ideas or identities rather than their geography or even time zone.

Web-based communities, social media sites, blogs, wikis and other online networking sites designed to facilitate communication between people offer an opportunity to connect individuals, allow them to share information and allow discussions and relationships that could not otherwise occur due to constraints caused by time or location. Like traditionally conducted action research, online action research also provides opportunities for empowerment of individuals who have been marginalized, democratic social change and community development, but potential exists for the participants in action research to increase in number and diversity as a result of the removal of time and geographic barriers.

Online action research can occur in a synchronous or asynchronous environment. Educational institutions have used an asynchronous, online learning environment increasingly, with some institutions offering entire degree programmes online. Much of the emergent research about online action research comes from action research studies based in the field of education and online professional development and certification and degree programmes. An initial benefit seen in online education that translates to online action research is the opportunity for participants to reflect on and evaluate both their own contributions to the online community and the contributions of other participants.

In a face-to-face interview, panel or town hall meeting, participants must process information and react immediately. Online action research participants can take time to reflect on words, ideas and their own experiences as they construct their own contributions to the virtual research, often yielding richer discourse as a result.

Online action research offers opportunities for reaching out to participants, fostering development and change and disseminating information in faster and more far-reaching ways than ever before. Online action research allows information to be shared immediately and globally and offers many potential benefits. However, many of the impetuses for action research, such as disparity, marginalization, discrimination, isolation from the community and lack of voice, remain prominent. Care must be taken to remember that access to technology does not eliminate these ills; online action research does, however, offer additional opportunities to reach those individuals who need and desire to create change.

In one Canadian study, Sarah Flicker, along with a team of action researchers composed of youth, community partners and university researchers, worked to develop a model (e-PAR) for using technology and PAR to address a problem specific to their context: engaging youth in community health promotion. These action researchers model what the combination of PAR and the Internet can offer: widespread accessibility to empowerment. Stakeholders came together using Photovoice to engage youth along with youth media and online tools such as electronic music and video production. Participants used some traditional tools of PAR as well as e-mail, websites, online surveys, online 'zines, and web exhibits in their collection of data and dissemination of ideas and results. The potential for change and empowerment to individuals and groups continues to increase as individuals become more accessible and connected to one another through online resources such as social media and networking sites, blogs and rapidly developing virtual communities.

ONTOLOGY

Within analytic philosophy, ontology refers to a branch of metaphysics that aims to dissect the underlying structure of reality. Ontology may also be concerned with the meaning of being or used to demarcate distinct positions towards the underlying nature of reality. It is this latter concept that is used here, with the aim to show how different positions towards reality may inform action research. An examination of ontology in action research is important because ontological positions inform the nature of the relationship between the subject and the object or between the knower and the known. How these relationships are conceived has a bearing on approaches and outcomes in conducting research.

Broadly speaking, ontological positions may be placed along a continuum. At one end lies an objectivist position, and at the other lies subjectivism. These positions differ most drastically from one another in their adherence to the assumption that reality exists

independent of human input. Various ontological positions may be used to approach action research. However, two fundamental aims of action research influence the discussion of ontology: (1) the participatory role of the action researcher and (2) the quest of the action researcher to change the underlying structure of reality in an effort to promote justice, equality or democracy. These aims will be addressed in turn, and their methodological implications will be examined.

Realism is an ontological position which posits that reality exists independent of the human mind and is governed by causal laws and mechanisms. Under this view, inquiry aims to objectively describe entities in the actual world, whether observable or unobservable. There are many strands of realism, which can be distinguished from one another in terms of the extent to which reality is presumed to be directly observable. This position naturally aligns with objectivism, which generally aims to ascertain a singular truth about a given reality.

A relative ontological position assumes that reality is essentially constructed. These realities are characteristically social or individual and, as Émile Durkheim held, depend on social factors for their existence. This ontological position is widely embraced by constructivists. In this view, elements like thoughts, emotions or social structures like family or social groups are assumed to be as real as the meanings we associate with them. Therefore, entities in the world are mind dependent and relative to particular contexts. More radical relative views deny the existence of reality apart from human constructions. As such, the aim of inquiry under these views often entails underscoring how constructed realities act to shape human consciousness.

Scientific realism is a hybrid of realist and relative ontologies in that it treats physical and constructed entities as equally real. This position departs from realism in the extent to which reality is accessible via inquiry (i.e. epistemology). Within the social sciences, scientific realism is manifested as critical realism, as espoused by Roy Bhaskar (1986) in his work *Scientific Realism and Human Emancipation*. In *A Realist Approach for Qualitative Research*, Joseph Maxwell (2012) characterized this approach as retaining a realist position ontologically while embracing epistemological constructivism or relativism. For example, scientific or critical realism proclaims that the aim of inquiry should be to describe reality independent of human input while also recognizing that this effort is at best an approximated ideal. In other words, critical realism contends that human input indeed matters and contributes to the fallibility of knowledge about reality.

Historical realism views reality as a product of historical processes. When conceived thus, reality is constructed and reified through social interaction.

Virtual, constructed realities acquire a 'real' objective and sometimes immutable quality through time and historical existence. This ontological position is widely embraced in critical theory and its related ideological positions. For example, Karl Marx and Friedrich Engels advocated for a form of dialectical materialism, wherein historical forces grounded in economic modes of production act to shape individual consciousness.

Finally, subjectivist ontology illustrates the most radical departure from realism in that this position assumes that reality is a property of the mind. For example, the social constructionist may argue that there is a reality beyond the mind, though the meaning derived from this reality is inherently social. The subjectivist on the other hand rejects this view by arguing that the mind itself completely imposes meaning upon reality. Philosophical positions like postmodernism, idealism and transcendentalism are rooted in subjective ontologies. Broadly speaking, the aim of inquiry under this ontological position entails deconstructing individual or social reality.

The Participatory Role of the Action Researcher

Framing the discussion on ontology in action research is the juxtaposition of the knower and the known, and the subsequent collapse of the ontological and epistemological distinctions, through research engagement. As a methodological approach, action research values deep engagement between the subject and object. This is because popular areas for application of action research include business and organization studies, nursing, health care, education, development studies and social and community work. These areas of application are characteristically social and dynamic in nature. Action researchers argue that in order to study social contexts, it is required that the researcher's role is that of a participant in reality rather than a detached observer. Consequently, this places the researcher in the same ontological position as the reality being examined. Put differently, by virtue of direct participation, the researcher becomes both the knower and the known, and this problematizes the traditionally established distinction between subject and object.

The participatory nature of action research also facilitates the collapse of ontological and epistemological distinctions. While ontology deals with the nature of reality, epistemology is concerned with the nature, limits and justification of human knowledge. Maintaining clear lines of distinction between ontology and epistemology is largely seen as essential for maintaining objectivity in research. The collapse of ontological and epistemological distinctions raises questions about the objectivity of findings when using action research methodology.

The Aim of the Action Researcher to Change Reality

Ontologically, action research is concerned with states of reality that are dynamic and changeable by human agency. Additionally, the action researcher, through reification, actively aims to bring new realities into being. Therefore, one can conclude that reality in action research is necessarily mutable as an immutable reality is inconsistent with the aims of action research.

This aim of the action researcher to change reality is value laden. Reality, as seen through the eyes of the researcher, can be assumed to be 'good' or 'bad', 'just' or 'unjust'. Thus, the action researcher can attempt to maintain the status quo, deconstruct or demolish structures of power and authority, solve problems or democratize social structures through participative interaction. While the methods used to change reality may vary depending on the philosophical position (e.g. Marxian, Freirian or Gandhian), action researchers are united in the aim to change reality. This ontological position stands in direct contrast to objectivist inquiry that aims to examine reality unimpeded by human input.

Methodological Implications

As implied earlier, action research is concerned with the particular, as opposed to the universal, and this contrasts with the dominant scientific discourse aiming to discover deterministic laws governing reality. Therefore, action researchers naturally align with ontological positions like social constructionism, historical realism or critical realism as they provide a framework to challenge dominant practices framing the study of reality. Consequently, action research legitimizes realities created through means like transcendentalism or even mysticism as having substantive ontological implications.

While blurring the lines between object and subject reflects a growing skepticism and discontent with Enlightenment ideals, this stance has also implicitly separated the action researcher from the dominant discourse. It opened action research to critique. The critique is directed both at the core of the established ontology of action research as well as its epistemological application as a valid methodological approach.

The critique is that given the inseparable juxtaposition of the knower and the known via researcher engagement, there are no viable pathways to objective findings using action research. Some proponents of action research even admit that it is not possible to start out with a subjective or relative ontology and emerge with objective research findings. Without a pathway to objective findings, action research has been critiqued as a mode of individual expression rather than a serious methodological approach.

One response to the critique is the argument that the subject-object divide is not necessarily incompatible with action research. For example, it is conceivable for critical realism to guide action research, and there is a growing movement to defend realism as a viable ontology for qualitative research. However, the exploration of realist or critical realist ontologies is not without critique from some action researchers. The argument is that critical realism does not provide those bound by subjective ontologies with a pathway to objective epistemologies.

Other action researchers respond by rejecting the subject-object dualities denoting a separation between the knower and the known. Their approaches see reality as holistic rather than divided. Poonamallee, for example, argued that in Eastern philosophies like *Advaita*, reality is viewed holistically. Hence, the object can simultaneously be the subject and vice versa without compromising the integrity of the research. She offered a model for developing Grounded Theory in action research that originated in subjective ontology and despite blurring the lines between subject and object emerged with findings that, she argued, were aligned with objective epistemology. This approach claims that objectivity in action research emerges from the authenticity and trustworthiness of the researcher and the knowledge creation process rather than from a detachment between subject and object.

Summary

An action researcher can engage varied ontological positions depending on the nature of the research being conducted. For instance, when examining inequalities in the distribution of economic wealth, a social constructionist may focus on the negotiation of cultural meanings associated with being wealthy or successful. The critical theorist, on the other hand, may give ontological supremacy to sociopolitical realities like education or trade agreements that have created and sustained economic inequality. While one may approach action research through varying ontological lenses, action researchers remain united in their efforts to change the content of reality.

OPERATIONS MANAGEMENT

Operations management focuses on achieving customer service and productivity now and in the future. Performance goals may be defined in terms of quality, speed, dependability, flexibility and cost. Operations management thinking applies to any working unit within an organization which converts inputs (materials, information, people) into outputs (products, services) and which aims to satisfy a customer or client need efficiently and effectively, to succeed in a market, to increase profitability or to grow. In a competitive or resource-constrained environment, such growth and development are enabled ultimately by getting more from less through running and improving operations. The sustainability of this performance requires questioning and improving operations practices and performance in anticipation of or in response to changing resource availability and customer or client need.

Yet the working of an operation is an enigma. On the one hand, the operation is a visible part of the organization where people or equipment can be seen to be working and where something happens. On the other hand, the operation will neither come right nor stay right of its own accord. The improvement imperative permeates the routine, and the challenge for managers includes the exploration and exploitation of the learning emerging from practice and from the changing body of programmed knowledge. It is in this learning opportunity that the critical role for action research resides.

The Strategic Role of Operations

Operations play a strategic role for the organization, ranging from neutral to supportive, internally or externally. Learning needs and opportunities permeate the development of this strategic role as managers exploit their insights into practice and explore new opportunities emerging from experience.

Operations strategy thinking and action involve reconciling the requirements of the market with the

capabilities of operations resources. Problems and opportunities in operations strategy revolve around fit, sustainability and the risks attached to differing configurations of product or service offerings, process technology, capacity, supply networks and organization. The content and process of reconciliation involve improvement within the firm and between firms—the locus of improvement. The focus of this improvement can be operational or strategic. *Operational* improvement is evident in the change to operational performance. *Strategic* improvement is evident in the changed fit or the reconciliation of market requirements and operations resources beyond the time frame of the improvement initiative. In every improvement with an operational focus, there is a latent strategic focus.

Action Research in Operations: See the Layout, Hunt the System

The operations improvement process may be visualized as a cycle with three elements:

1. *Directing* (or co-directing in the supply network) improvement through comparing targets with performance
2. *Developing* (or co-developing in the supply network) operations capabilities through process control and process knowledge
3. *Deploying* (or co-deploying in the supply network) operations capabilities to create market potential

Action research fits with the improvement process and with the associated ambition to capture learning from practice. As such, action research is recognized as a valid methodology for research in operations management.

Through action research, managers and researchers collaborate around conceptually and managerially relevant operational problems. Enacting in a disciplined way a set of iterative action research cycles yields unique insights that deepen understanding, improve practice and extend theory. When working together, both the operations manager and the researcher need to take action—to experiment systematically—and to observe the workability of the operation. From this shared experience, they infer the manageability of the operation and evaluate its viability as run in this way. The outcome is a shared sense of areas for improvement and a process by which the improvements may be realized. In effect, the operations management and improvement challenge is condensed down to a single action-oriented statement: See the layout, hunt the system.

In seeing the layout and hunting the system, the manager and the researcher together are looking to understand where trade-offs have been made (and can be made if the operation is to improve) in the specification of needs, co-ordination of inputs, pacing of processes, rationing of resources, inspection of outcomes and change of control systems. Enquiring collaboratively, the manager and researcher together can identify operational performance data (on quality, speed, dependability, flexibility and cost) and financial performance data (profit, sales and cost trends). They can examine the significance of the operational data in relation to the financial data before attributing the financial outcomes to the way in which the operations resources (capacity, supply network, process technology, development and organization) are configured and run. Then, the manager and the researcher can consider the impact of changes in the operations resources on operational performance and attempt to predict how these changes might show up in revenues and costs.

Summary and Conclusion

In operations, something happens. A key focus of operations management is improving operations on an ongoing basis from a basis of experience. Such improvement activity is not once-off. It is a means of ongoing reconciliation of market requirements and operations resources within organizations and shared between them.

ORAL HISTORY

Oral history research is a method in which personal stories are elicited from people over their life course. It is a specific method of interviewing that requires the researcher and participants to spend a long time together in a process of telling and listening to life stories. Storytelling is a fundamental aspect of human experience; meaning is conveyed through storytelling. This way of passing on knowledge has allowed researchers to develop research techniques that provide an opportunity for people to make their voices heard.

An oral history often emphasizes a particular part of an individual's life—for example, work life or a specific function in some aspect of community life. The emphasis of oral history is on a specific historical juncture, event, period or location which is memorized by individuals. Oral history relies heavily on individual and collective memory and the testimony of participants. This will ensure that a fuller or different understanding of past experiences can be achieved. Importantly, oral histories have permitted the voices of groups who are usually marginalized in historical research to emerge.

Oral history affords researchers a way of inviting their participants to tell their stories of their past. But the individual story is often tied to historical existences and therefore goes beyond the person's experience. Oral history is especially crucial for studying how individuals experience social changes as well as the social and personal problems emerging from these changes. Oral history interviews allow participants to tell their stories on their own terms, so they are able to speak in the way they choose. Thus, oral history interviews function as ideal vehicles for understanding how people perceive their lived experiences and how they connect with others in society.

During an oral history project, researchers spend a lot of time with research participants in order to gain a comprehensive knowledge about their experiences or about specific aspects of their lives. Oral history methods allow researchers to obtain in-depth information about the lives of participants from their own perspective. Researchers learn how participants feel about things, what they consider important in their lives, how they see the relationship between different life experiences, about their difficult times, and the meanings they have constructed as members of society.

Oral history methods are popular among feminist scholars. Based on a feminist framework and a predominantly feminist method, oral history allows researchers to access the invaluable knowledge and rich life experiences of marginalized individuals and groups, which would otherwise remain hidden.

In particular, the methods afford a means of reaching marginalized voices. Oral histories allow the participant and the researcher to collaborate and generate knowledge, and this can be an empowering experience for the researched as they are able to gain insight into important moments in their own lives.

History of Oral History Research

The oral collection of historical documents can be traced back to ancient times. Three thousand years ago, the sayings of the people for the use of court historians were collected by historiographers of the Zhou dynasty in China. But the first official record of an oral historian is of the Greek historian Thucydides, who, centuries later, looked for people he could interview and used the interviewed information to write his history of the Peloponnesian War. Although personal stories have been collected since the fifth century BC, it was only after the Second World War, when portable recording machines were invented, that a more systematic record of oral history began, such as we see nowadays.

The formal organization of oral history research occurred in 1948, when Allan Nevins commenced the Oral History Project at Columbia University. Nevins' aim was to develop a record of the lives of important individuals in American society. His recording of the oral memories of White male elites became the first organized oral history project. Only after the 1960s did we begin to see more interest in the memories of non-elite people. William Thomas and Florian Znaniecki are among the pioneers of the narrative approach because they used it in their work with Polish emigrants to the USA. However, despite the endorsement of Thomas and Znaniecki, oral history did not become a popular method until much later when it became widely used in the feminist movement.

An important development in oral history is an attempt to collect the oral histories of oppressed groups in order to provide profound and telling stories that have been suppressed. In the past, only elite people could record their lives, not only because they were literate and believed that they were important but also because they had the time and the people to help them write. Because of their power in society, only their narratives are the ones we learn of from the official records.

Oral History and Action Research

Oral history research offers a valuable means for collecting information from local communities in action research, particularly Participatory Action Research (PAR). The essence of PAR is that the research begins with the problems that people face, and then they participate

in the research process as fully as possible. The research participants are full partners in the research process and are treated as co-researchers. Together with the researchers, they became involved in the research cycle to find solutions for their problems. Researchers adopting this methodological approach clearly aim to work collaboratively with people who have traditionally been oppressed and exploited. Collectively, fundamental social changes can be achieved through PAR. This is particularly so for Community-Based Participatory Research, which is a research approach which equally involves the community, such as community members, agency representatives and organizations, and the researchers in all facets of the research process. Community-Based Participatory Research empowers different groups to collaborate in research in order to appreciate and address the complex social, cultural, political and structural factors affecting the lives of individuals and their communities.

research. Definitions of OD vary, but they tend to comprise the following elements in one form or other: that OD is a long-term effort whose aim is to improve an organization's processes of renewing itself through envisioning its future, structuring itself appropriately and being able to solve problems. OD places special emphasis on an ongoing management of organizational culture, particularly in work teams and interdepartmental configurations. It may utilize an external OD consultant, who works in a facilitator role rather than an expert advisor role. This entry discusses the history and characteristics of OD, as well as interventions and OD's core feature, action research.

History

OD does not comprise a single theory, and so its origins lie in many different strands of applied behavioural science—individual psychology, group dynamics, leadership, organization theory, human resource management and elements from sociology and anthropology. In some respects, OD builds on all the major developments of organization theory and the interface of organizations with the people who work in them. Some of the experiments and research which are more directly related to the emergence of OD as a distinctive approach to managing planned change are as follows: (a) the work of Kurt Lewin on re-education, planned change, field theory, the stages of change and action research and his seminal work on group dynamics, and, in particular, the emergence of T-groups; (b) the work of Eric Trist and his associates in the Tavistock Institute in the UK on coal mining in Durham, which led to an understanding of how technology and people are interdependent and how organizations are socio-technical systems; (c) the client-centred approach to helping individuals make their own personal change pioneered by Carl Rogers and (d) the approaches to surveying organizations developed by Rensis Likert and his colleagues in Michigan.

Much of the development of OD came out of Lewin's discovery that attention to 'here-and-now' processes in a group provides a powerful vehicle for learning about groups. This insight was formalized in the T-group ('T' stands for training), which is an unstructured group led by a trainer who works in a non-directive manner. T-groups were organized by the National Training Laboratories (later the NTL Institute), which was founded by Lewin's associates. NTL and T-groups are the most significant sources of origin of OD because (a) of the philosophy of the T-group, namely, the trainer works in a non-directive manner, and learning takes place out of what is happening in the group (a paradigm of action research) and (b) the pioneers and significant developers of OD were T-group trainers in the NTL

ORGANIZATION DEVELOPMENT

The term *organization development* (commonly referred to as OD) refers to an approach to organizational change that is a philosophy, a professional field of social action, a mode of scientific inquiry and an array of techniques to enable change to take place in organizations. It is understood to be different from *organizational development*, the latter referring to the general development of organizations and paralleling terms like *personal development* and *community development*. OD is understood to refer to a specific values-based approach that has its roots in the work of Kurt Lewin and which is deeply imbedded in action

Institute. It was when the T-group was being applied to working teams that the focus and term *organization development* emerged. In Britain, the Tavistock Institute developed its own form of the T-group in the Tavistock Conference, and its work on socio-technical systems paralleled OD.

In the 1960s, 1970s and 1980s, the leaders of OD were those who had come through the T-group learning system and who shaped the emergence of this distinct approach to change. The early pioneers of OD, the colleagues of Lewin, recruited a next generation, who in turn educated and trained a third and a fourth generation. In 1969, the publication of the Addison-Wesley OD series marked the formal emergence of the field. The initial six books in the series, edited by Richard Beckhard, Warren Bennis and Edgar Schein, demonstrated the variety and range of approaches within this field. By the late 1990s, there were over 30 books in the now defunct series. *The Journal of Applied Behavioral Science* was the primary outlet for research and theory development, while *The OD Practitioner* addressed the needs of practitioners. Universities and colleges offered postgraduate programmes in OD; college textbooks and other books and articles followed. OD became a field of study and practice. Associations such as the OD Network and the OD Institute provided fora for practitioners to discuss their practice and the Organization and Change division of the Academy of Management, for scholars to present their research. While there were attempts to make it a profession through establishing a registration and a code of ethics, these efforts were not successful; and OD remains a broad field to which anyone can designate themselves.

The early approaches placed a great deal of emphasis on individual and group development. The task-focused nature of working teams in organizations and the hierarchical relationships within an organization's structure challenged the T-group trainers to redefine their work beyond the personal learning in an egalitarian setting. The emerging field of OD was working with large, complex systems and engaging with issues of strategy, leadership, organizational design, technology, human resource development, organizational learning and latterly sustainability.

What was distinctive about OD in the 1960s, 1970s and 1980s was that it followed a cyclical process of consciously and deliberately (a) diagnosing the situation, (b) planning action, (c) taking action and (d) evaluating the action, leading to further diagnosing, planning and so on. The second dimension is that OD was collaborative, in that, with the help of a consultant/facilitator, the members of the system participated actively in the cyclical process. It engaged people as participants in seeking ideas, planning, taking action, reviewing outcomes and learning what worked and did

not work and why. This approach was in stark contrast with programmed approaches that mandated following pre-designed steps and which tended not to be open to alteration. These latter approaches were based on the assumption that the system should adopt the entire package as designed. OD was based on the assumptions that each system is unique and that a change process has to be designed with that uniqueness in mind and adapted in the light of ongoing experience and emergent learning.

The emergence of a more general field of change management, which grew out of OD, spawned approaches to studying and engaging with organizational change that sought to differentiate themselves from OD by challenging participative approaches and focusing on top-down imposed change and bottom-line outcomes. Change management approaches became identified with a more prescriptive approach as consulting firms, acting in an expert model, perform a diagnosis of an organization and submit a report that prescribes actions. The popularity and predominance of these firms and the emergence of programmes in change management in university curricula led to a debate as to whether OD had lost its purpose, and indeed whether or not OD was dead. From an OD perspective, OD is different from change management as it has a discomfort with some of the contemporary change management approaches, such as re-engineering. In short, OD's humanistic values base focuses on process, while change management focuses on outcomes.

While OD's origins lie mainly in change in business organizations, it has developed to become applicable in education, health care, non-profits and government organizations, and there is an extensive literature on OD in each of these sectors. In parallel, OD has developed beyond its original Anglo-Saxon roots to be applicable in all cultures.

Characteristics

While there are many characteristics of OD, the central ones emphasize employee participation in discussing and analyzing critical issues for change and in finding and implementing solutions and evaluating the results. OD is normative in that it advocates that those in the organization who are affected by the change should have the opportunity to contribute to the continuous-improvement process. It is based on the assumption that everyone implements change in organizations.

The following characteristics mark the distinctiveness of OD as an approach to managing change. These characteristics distinguish OD from a more general change management approach. OD is a process for building healthy, high-performance organizations and

improving and realizing the full potential and self-renewing capabilities of organizations, groups and individuals. It is also an education-based strategy that uses a positive and constructive approach to successfully leading and managing change. It is an interdisciplinary approach that draws primarily from the applied behavioural sciences (e.g. psychology, sociology) and uses understanding of business and the influence of technology on organizations. It is values driven and seeks to instil values and build cultures that bring out the best in organizations and people and to encourage open, straightforward, helpful, ethical and increasingly self-directing behaviour. It is a facilitative process that helps others discover and find solutions to their own issues. It relies on a systems perspective of organizations that considers all aspects of an organization and its interrelated parts. It is a data-driven, action research-oriented approach that includes assessing reality and involving key stakeholders in evaluating results, exploring what is possible and planning further action. It is a collaborative top-down, bottom-up process that recognizes the importance of building the commitment and leadership of top-level decision-makers and involving all stakeholders in the change process. It focuses on both process (how things are done) and content (what is done), recognizing the importance of both. It is often guided and facilitated by professionally trained change agents, both external and internal. It is committed to the transfer of knowledge and skills and to creating learning organizations where organizations and their members are continuously learning, sharing knowledge and improving the organization. Finally, it emphasizes the importance of planned, lasting and sustained change, rather than the quick fix, while at the same time developing the organization's ability to adapt to changing times.

New forms of OD have emerged in the late twentieth century, influenced by the new sciences and postmodern thought and philosophy and views of organizations as meaning-making systems. Accordingly, contemporary OD views reality as socially constructed, with multiple realities which are socially negotiated rather than a single objective reality that may be diagnosed. Data collection is less about applying objective problem-solving methods and more about raising collective awareness and generating new possibilities which lead to change. Contemporary OD emphasizes changing the conversation in organizations by surfacing, legitimating and learning from multiple perspectives and generating new images and narratives on which people can act. Accordingly, the focus of OD is to create the space for changing the conversation. A feature of the newer forms of OD is the large-group intervention. While these large-group interventions have different names—Search Conferences, future search, open space, among

several terms—what they have in common is the notion of bringing the whole system into the room and engaging in conversation about present realities and how to create future realities. While large-group interventions have had their origins and expressions in traditional OD, they have flourished in the way they provide a setting for multiple perspectives to be shared and how they aim to develop a new shared vision and agenda for change. In a similar vein, Appreciative Inquiry has developed as a constructivist approach that aims at large-system change through an appreciative focus on what already works in a system, rather than what is deficient, and has an underlying capacity to leverage the generative capacity of metaphors and conversation in order to facilitate transformational action.

OD Interventions

An intervention is understood to mean an action or a series of changes aimed at changing the status quo. Within the complexity of organizations, there are multiple interventions that could be made. Accordingly, efforts to group or cluster interventions are important, especially in the education and training of OD scholars and practitioners. Three basic clustering frameworks are established. One is to cluster OD interventions into three main groupings that identify three clusters based on the focus of intervention (i.e. limited, focused and holistic). Another approach clusters four processes: (1) human processes, (2) socio-technical approaches, (3) human resources and (4) strategic approaches. A parallel framework emphasizes the focus of intervention: individual, group, inter-group and organizational. A wide range of specific interventions may be located within these two frameworks: for example, career work and coaching on the individual level, team building and maintenance on the group level, workflow processes and inter-group relations on the interdepartmental group level and strategic issues on the organizational level. These two frameworks may be merged as some individual interventions may be classified as human processes, others as human resource interventions.

OD and Action Research

Action research is one of the distinctive features of OD and one of its core origins. For Lewin, it was not enough to try to explain things; one also had to try to change them. This insight led to the development of action research and the powerful notion that human systems could only be understood and changed if one involved the members of the system in the inquiry process itself. So the tradition of involving the members of an organization in the change process, which is the hallmark of OD, originated in a scientific premise that this

is the way to (a) get better data and (b) effect change. Action research is based on two assumptions which are the cornerstones of OD. One is that involving the clients or learners in their own learning produces not only better learning but also more valid data about how the system really works. The other is that one only understands a system when one tries to change it, as changing human systems often involves variables which cannot be controlled by traditional research methods. Accordingly, a central element of the OD approach is a reflective approach, which goes with the story as it evolves rather than imposing defined programmes as discussed above.

Action research used with OD is based on collaboration between the behavioural-scientist-researcher and the client on exploring issues and generating data on the development of the organization (the research activity) and on jointly examining the data to understand the issues. They then develop action plans to address the issues and implement them. Together they evaluate the outcomes of the actions, both intended and unintended. This evaluation may then lead to further cycles of examining issues, planning action, taking action and evaluation. Cyclical-sequential phases may be identified that capture the movements of collaboration from the initial entry through planning and action to evaluation. These activities may serve also to generate new behavioural science knowledge, which is fed into the depository of information for other behavioural scientists as general laws, types of issues or the process of consultant-client collaboration, thus addressing issues beyond the specific case.

Through the nature of action research in OD as a collaborative, interventionist form of research, grounded in its Lewinian roots in the scholarship of practice, OD has the capacity to bridge the rigour/relevance, theory/practice divides that beset contemporary organization studies. This demands that the OD scholars attend explicitly to their own learning in action, to the dynamics and quality of their engagement of OD with a client system and to the generation of actionable knowledge. While the academic world has struggled traditionally to accept such forms of inquiry and action as 'scientific', in the postmodern world this is increasingly less so. In today's context, there are increasing demands for organizational research to be rigorous, reflective and relevant. OD through action research continues to provide such rich possibilities.

OD through action research is continuously evolving as it has the ability to adapt and respond to the variety of emerging challenges experienced by individuals, groups, organizations, communities and societies. It is reflexive and continues to be self-aware, and to be open to its own learning and development, in the light of emerging economic, social and business

trends and learning how to be relevant in each generation. It involves collaborative research in that it has always espoused research *with* people rather than *on* or *for* them. At the core of most OD work, there is commitment to the generation of scientific knowledge that can guide practice. OD work is embedded in relationships—between OD practitioners and clients, between OD scholars and clients, between members of the system who are involved in an OD project, between OD practitioners who work together and between OD scholars and OD practitioners—the quality of which has a direct impact on both the process and the outcomes of any OD project. OD continues to focus on the sustainable development of human, social, economic and ecological resources. OD through action research is relevant in any context. While each context has its own particular characteristics and challenges, the core values and processes of OD and action research have remained relevant.

ORGANIZATIONAL CULTURE

The term *organizational culture* refers to the unique character of an organization that provides the context for action in it; it places an emphasis on the traditions, structure of authority, behaviours, espoused values, language, mission, paradigms, symbols, standards, traditions, customs and group norms. Edgar Schein describes organizational culture as a phenomenon that surrounds all within the organization and refers to the pattern of shared basic

assumptions learned by all in an organization that are passed on over time.

With time, this pattern can become deeply entrenched and, with that, very difficult to change. Where organizational culture is deeply entrenched and rooted, it affects the people within the organizational system. While this is so, the people within an organization are not passive victims of an organizational culture; they also bring their agency and in turn shape the organizational culture.

From the description of Schein, it is evident that culture is fundamental to the understanding of organizational life. However, there needs to be a recognition that there are different orientations to understanding culture in organizations. One of the orientations, according to Schein, is the structural-functionalist view. In line with this orientation, culture is the created and transmitted content and patterns of values, ideas and other symbolic meaningful systems as factors in the shaping of human behaviours.

Flowing from this orientation, organizations are viewed as mechanistic structures, and individuals learn or are socialized into the culture of an organization. This makes culture a static phenomenon within which is embedded the system of expectations that individuals have to conform to. Viewed from such an orientation, culture becomes a social fact that bears an ideological message, and individuals have to be integrated into the organizational structure.

The culture of an organization is more acutely experienced by individuals who are new—it may happen that they are coerced or socialized into it. Commonly, the coercion or socialization is not obvious; it is subtle. For example, in an organizational system where a particular language is used, the new people often pick it up without realizing what is happening to them. Within no time, it becomes second nature, and they start sounding like those individuals who have been there much longer. Whether they are coerced or socialized into it, those who are new in an organization respond differently to the organizational culture; while some are able to embrace the new culture with ease, others find it difficult, and their resistance manifests in inappropriate behaviours.

Another orientation is one which recognizes and acknowledges the agency of individuals and makes them active shapers of culture in organizations. Concomitant with this orientation, culture becomes a dynamic phenomenon which arises out of the individual's interaction with the organizational system—the connection between the individual and the collective is central. This orientation requires that organizations be viewed as dynamic systems that hold a space for culture to be created by change and process—linked to this, the processes through which individuals and

the collective negotiate meaning are therefore critical. One such process has to do with the creation of subcultures in organizations. Subcultures stem from situations where individuals or groups dissociate themselves from the dominant culture. While generally not appreciated in organizations, subcultures can provide an impetus for change in organizations.

Sue Soal suggests that organizational culture is the very expression of the character of the organization and, together with the vision, mission and strategy, constitutes the identity of the organization—the identity expresses the outer purpose of the organization. The organizational culture expresses its inner character and work—it defines the way in which its work is pursued.

The 'Organizational Invisible'

Organizational culture is often referred to as the 'organizational invisible'; it becomes visible through observable forms such as language, rituals, symbols, ways of dressing, behaviours, shared meanings, shared knowledge and practices. Though invisible, the underlying culture can be viewed as an explicit product that arises from social interactions between people that can shape the way things are done in an organization in a very powerful way. For example, the way people dress in an organization is one aspect that can reflect the power of its culture. In a context where the culture dictates an 'informal' dress style, this is picked up remarkably quickly by new people, who prefer a much more relaxed atmosphere. They embrace the dress style dictated by the organizational culture without question.

It is the 'invisible' aspect that makes it difficult to work with organizational culture. When attempting to change organizational culture, it is important not only to focus on the visible dimensions but also to pay attention to the underlying processes at work. For example, in a situation where there is no trust, it can become pointless to try and understand the learning practices without trying to understand and grasp what the underlying processes and issues are that contribute to a culture of mistrust. Often, when trying to understand the factors that inhibit learning in an organization, one has to dig deeper and try and understand what the underlying culture is—the factors that inhibit learning are often rooted in the culture.

One of the characteristic features of organizational culture is that it is holistic and manifests in all aspects of organizational life—the mission, values, practices, relationships, rituals, customs and way of thinking. It is common though for such manifestation to be experienced more acutely at the level of interpersonal relationships. In fact, organizational culture can manifest often as fraught with interpersonal relationships that,

when attempting to address them, take the focus away from the essential and critical aspects. For this reason, it is important that organizational culture is understood as multilayered and to acknowledge that it encompasses both the formal/informal and light/shadow attributes of the organization.

The Experience of Organizational Culture

It is for this reason that culture is experienced differently by different people in the organization. While some people may be comfortable with the formal aspects of the culture, others may relish its informal aspects. In addition, while there is a tendency for an organization to focus on the light (positive) aspects of its culture, the shadow (negative) aspects of its culture often make individuals uncomfortable—shining a light on the shadow aspects of the organizational culture can lead to denial, defensiveness and avoidance. For many organizations it is often difficult to face and engage with the shadow aspects of the culture with honesty.

Although organizational culture cannot be described as bad or good, it can be conscious and healthy or dysfunctional. To prevent the organizational culture from becoming dysfunctional, it has to be supported by relevant systems. When this is the case, it can help individuals cope with challenges pertaining to the broader social environment. Where no such organizational systems and processes are in place, people can end up frustrated by the organizational culture. Where mistrust characterizes the organizational culture, the presence of regular meetings can be a helpful support for creating a space for honest engagement. In the absence of such systems, the mistrust can fester.

Sue Soal suggests that culture changes slowly and in incremental moves. For some individuals, the process of experiencing the culture of the organization can be painful and hard, but not in the same way that the process of attempting to change the culture is. This is so because it is not possible to work on the organizational culture directly. In fact, understanding organizational culture is not easy; the multilayered nature of culture makes it difficult to single out or name, let alone change. In many instances, it takes comprehensive knowledge, well-developed skills, a deep understanding and insights to change the culture of an organization—without these it is easy to get lost.

Organizational Culture and Action Research

It is in this regard that action research as an exploratory inquiry into shifting and changing organizational culture becomes important. An action research approach,

structured fundamentally around inquiry, enables organizations to surface the presence and intensity of the organizational cultural attributes that enable or inhibit organizational renewal—it lends itself to dealing with the complex nuances of culture in organizations. Given the invisible, elusive and multilayered nature of culture in organizations, an action research approach allows for organizational culture attributes to be surfaced and interrogated through a structured process—it enables cultural attributes to be surfaced in a way that allows for organizations to negotiate the meaning of such attributes in a systematic way.

Given that culture changes slowly, an action research approach allows for exploration of organizational culture through the use of questions, stories, reflection and dialogue. These are powerful tools because they allow for meaning making at the individual and collective levels. Action research as an approach to exploring organizational culture as a complex phenomenon allows individuals and the organizational system to engage with it in a way that helps with the identification of learning edges—it enables change and process.

ORGANIZATIONAL STORYTELLING

While there has never been a time when stories have not been told in organizations, the formalization of the phrase is of recent origin. It now involves a broad range of practices from academic research to workshop facilitation and management consultancy. As such, there is no single agreed-on definition or even definitions. The range of theory and practice can be mapped between three basic functions:

1. The common use of storytelling is to communicate a message. With that, but rarely mentioned by practitioners, is the associated meaning of ‘telling stories’, namely, to lie, deceive or persuade, which in popular use includes propaganda. A focus on teaching leaders to tell a better story was one of the early drivers of the organizational storytelling movement, and it remains a feature, although the field is now more diverse.
2. Organizational stories are used to understand the nature of organizations and why people do what they do. In the main, this is a research agenda but can include a range of facilitation and consultancy techniques, such as Appreciative Inquiry, to facilitate self-understanding and interpretation.
3. Finally, and most recently, stories are used as a means of knowledge storage and transfer. Modern-day approaches draw on a broad range of subjects including cultural anthropology, communication theory and sense making. Some early experiments have taken journalism as a metaphor and as practice. These include journaling and other services within social computing that allow people to create family and community stories online.

These three functions of storytelling may play a central role in action research as experiences are explored and knowledge generated from both the stories themselves and the act of telling them. In practice, most of the tools and techniques include aspects of two or more of these dimensions, and the field resists rigid categorization. Organizational storytelling is now a broad field, with consultancy practice interacting with more academic research. Its origins lie with work in government and industry associated with the development of knowledge management during the 1990s. Both the World Bank and the IBM Institute for Knowledge Management (IKM) determined that stories told in the field had higher utility for capturing and distributing knowledge than best practice documents. This is equally valid in military doctrine. The US military started to capture stories in the field in their early knowledge management programmes. Intel and Jet Propulsion Laboratory (Part of NASA) brought in journalists to capture the key stories of employees who were due to retire and created libraries of that material which could be accessed by future generations. The IKM built some of the early experimental narrative databases, and a range of consultants both large and small started to add storytelling and capture into their methodologies.

In parallel with this, the BBC, in their Capture Wales project, and others were experimenting with what has

come to be known as Digital Storytelling, the origin of which is often traced to Ken Burns’ pioneering history of the American Civil War. This approach brings together people from a community, who with the support of journalists and production staff, create short visual stories that explain and record a key aspect of their lives. These are stored and accessed digitally. Partly in consequence of this, a range of open source and commercial social computing sites were created to allow communities and families to record their stories as a living oral history. Workshop techniques such as Appreciative Inquiry, with their focus on narrative as an agent of change, also gained currency during this period.

From the early use in knowledge management, the commercial use of stories gained interest from the long-standing communities interested in storytelling for its own sake. The Jonesborough National Storytelling festival in the USA created a forum for those interested in storytelling from community-based and commercial perspectives to exchange information and knowledge. In turn, the Golden Fleece Movement in Washington integrated work with that of the IKM and the World Bank. This integration of traditional storytellers (and those who studied them) together with technology-oriented knowledge management was a large part of the growing popularity of the associated techniques. The IKM further extended this work into techniques to derive archetypes from stories, to match work done by Joseph Campbell on the role of archetypes in *The Hero’s Journey* and other traditional stories.

Within the academic community, the use of story in research is well established, and in the main, preceded the organizational form. It engaged with the wider issue of observer independence within social science. Barbara Czarniawska challenged the *Homo economicus* assumptions of organizational science, arguing that the narrator and the listener must assume a shared context when inferring meaning from narrative statements, and further that as stories carry with them ambiguity, the meaning can be interpreted in different ways in different contexts. David Boje coined the term *antinarrative* to describe the process of linking retrospective narrative to a living story. The publication of *Storytelling in Organizations* by Yiannis Gabriel provided a bridge between the new communities in the work of the IKM and others. This was augmented by the use of narrative in the sense-making literature, in particular the work of Karl Weick and Brenda Dervin, both of whom in different ways see narrative as a fundamental aspect of the way people make sense of the world.

The growth of social computing created a new medium, both as a mechanism for the recording and distribution of stories and with whole new forms such as blogs and microblogging (Twitter). The US Army, one of the pioneers in the use of field narrative to create

doctrine, discovered that company commanders' blogging and stories captured through a West Point programme had more impact on field operations than doctrine.

With increasing use, issues of ownership (or power), authenticity and scaling of programmes, including the use and potential control or abuse of social computing, have come to the fore. This has resulted in approaches that focus on self-interpreted micro-narrative, linked to complex adaptive systems theory, which challenge the qualitative nature of most narrative work with a quantitative approach through either self-signification or the use of various algorithmic and other search and consolidation techniques, including the extensive use of visualization.

P

PARTICIPATORY ACTION RESEARCH

Participatory Action Research (PAR) is a research paradigm within the social sciences which emphasizes collaborative participation of trained researchers as well as local communities in producing knowledge directly relevant to the stakeholder community. The knowledge produced through PAR does not just intend to contribute to the theoretical corpus of the social sciences, but it also inherently contains an agenda of social change. As such, the ends of PAR include (a) developing and fostering a participatory model in social science field research, (b) preferring a practical form of knowledge-in-action to an empirical form of knowledge-as-statistic, (c) mobilizing local communities to have a concrete role in solving their own problems in an effective and systematic manner, (d) making development policy interventions, (e) advocating for inclusion of local stakeholders—their experiences and forms of understanding—in socio-economic theory and policy and (f) attempting to correct power imbalances in knowledge and information flows.

This entry outlines the historical emergence, principles, processes, methodology, challenges and ethics of PAR, with a discussion of some of its interventions.

History

The origins of the PAR paradigm can be traced to Europe, to a climate of critique of mainstream social science research, popular education models and social movements in general.

In 1940, the German social psychologist Kurt Lewin held that social science research must reject the positivist outlook of science, which prefers that researchers study an ‘objective’ world separate from the ‘subjective’ meanings understood by agents as they act in the world. He coined the term *action research* to describe

a process in which social scientists worked collaboratively with a group, organization or community that had stakes in the issue at hand. Action research emphasized a problem-solving approach to research and rational decision-making by a group aided by an external facilitator. The underlying principles of action research—self-reflection and critique through dialogue, collaboration, mutual learning and action—formed the basis of PAR. Somewhat conservatively, Lewin’s work placed relatively less emphasis on active community participation and did not challenge existing power relationships. Yet it provided a useful way of combining theory and practice to facilitate organizational change.

Another significant influence on PAR was the Brazilian educationist Paulo Freire’s *Pedagogy of the Oppressed* (1970), which evolved from his experience with adult literacy in Brazil and highlighted the power of education as a political tool for stimulating the consciousness of oppressed people. Freire’s notion of ‘conscientization’ reinforced the idea that socially marginalized people, through dialogue, can critically analyze their own situation as well as organize action to improve it.

His *thematic investigation*, employed in 1973, first in Brazil and later in Chile, inspired scholars and activists to collaborate with community residents to bring about community-controlled social change projects whose central principle was learning through investigation.

International adult education movements, particularly in Africa, Asia and Latin America, also set the stage for PAR. The philosophy of adult education focused on a learner-centric approach, yet adult educators had to adopt a research-centric approach in understanding the programme content and educational methods. This precipitated a crisis of identity, with adult educators questioning the dichotomy between their two distinct roles as in-field practitioners and off-site researchers. An alternative research paradigm was sought, which was learner-centric and required popular community mobilization.

During the early 1970s, Marja Liisa Swantz and her team of social scientists working as aid specialists in Tanzania found that students and village workers were far more effective than trained adult educators in eliciting the required information from people. Attributing this success to data collection methods that relied on communal sharing of locally specific knowledge, Swantz proposed that both the researcher and the researched could become agents of development and change. The new practice among adult educators of relying on local knowledge for technical solutions of local problems began to be known as 'participant research'.

The term *participatory research* (PR) was first coined in the 1975 special issue of the journal *Convergence*, featuring many grass-roots research projects. The group of featured practitioners, scholars and activists subsequently formed the 'Participatory Research Network'. The five geographical nodes of this network, and their respective chairpersons and centres, were as follows:

1. North America (Budd Hall in Toronto, Canada)
2. Asia (Rajesh Tandon in New Delhi, India)
3. Africa (Yusuf Kassam in Dar es Salaam, Tanzania)
4. Europe (Jan de Vries in the Netherlands)
5. Latin America (Francisco Vio Grossi in Caracas, Venezuela)

The network became a channel through which PR would gain wide visibility. A series of meetings were organized to increase awareness, deepen understanding, support users and highlight the universal resonance and relevance of PR.

The specific phrase *Participatory Action Research* was coined by the Colombian sociologist Orlando Fals Borda upon his interaction with the Latin American network of participatory researchers. The term described a variety of community-based approaches to knowledge creation which combined social investigation, education and action in an interrelated manner. Fals Borda gave PAR its worldwide recognition in the Cartagena Conference on Action Research in Cartagena, Colombia (1977).

The emergence of PR in the developing world and the political activism accompanying the social movements of the 1960s and 1970s sparked off a variety of PR projects by North American social scientists. John Gaventa, for instance, investigated political and economic oppression in Appalachian communities and grass-roots efforts to challenge the status quo. Peter Park engaged in the dialogue and uses of PAR in social movement contexts. Patricia Maguire articulated the need of feminist PAR.

By the 1980s, PAR was linked to alternative ideas about 'development'. Its central tenet was that if development was for the people, then as primary stakeholders in the development processes, people themselves should represent their case in the stage of knowledge generation as well as of its use. It drew strength from debates around participation in development programmes, questioning the top-down design of development policy.

Principles

Empowered Participation

Participation is the primary core principle of PAR. Unlike conventional social science research, PAR actively engages participants in all aspects of the research process, from design to dissemination. The participation moves from phases of passive participation to more interactive participation and finally to self-mobilization. A lower degree of participation, designated as 'non-participation', takes place when participants are only superficially involved in decision-making, the actual influencing power remaining in the hands of one powerful group or person. Participation is 'tokenistic' or 'symbolic' when potential participants are just informed about the objectives of research, but the project as such is still designed and led by more experienced researchers. Real participation or power sharing takes place when the decision-making processes are structured to incorporate negotiation between participants and those in power, with consensus as the eventual aim. Neither participants nor researchers can unilaterally enforce their point of view on each other. The participants have a role as well as a voice in the decision-making processes. They initiate, organize and lead defined research activities. In the self-mobilization stage, participants have full sovereignty and responsibility for organization, execution and monitoring of the entire research.

Commitment to Action and Social Change

The goal of PAR is to fundamentally transform social relations—helping those with less power and fewer resources get more of the same. Marginalized communities often lack relevant information to improve their conditions. The kind of information that PAR produces can clarify the issues and challenges facing them, create awareness of the need for action, focus attention on specific areas of concern, identify resources, design strategies for change and assess the impact of those strategies.

Its agenda for social change orients the PAR process towards solving problems rather than conducting research for the sake of advancing knowledge. The

process begins by equalizing the relations of power between the professional researcher and the members of the community being studied. The key belief of PAR is that change happens when the subjects of research learn to use new knowledge to reflect upon their own situation and then participate systematically and critically to overcome challenges and difficulties.

Collaborative and Equitable Research

In conventional research, the existing power relations between the researcher and the subjects of research are often taken for granted, and the impact they may have on the research goes unexamined. Such research tends to serve the objectives of those in power simply because they are economically, politically and socially better positioned to determine what questions are asked as well as how the findings of the research are to be utilized. In PAR, however, every participant contributes his or her expertise and shares in responsibility. This collaboration goes a long way in increasing trust and in bridging cultural gaps between partners.

Process

PAR begins with issues emerging from the day-to-day problems of living. Ideally, the actors-cum-researchers in a particular social setting conduct their own research geared towards changing their own situation. But often, a community may be unable to clearly articulate its felt problems. Here, the participatory process incorporates researchers from the 'outside', who work with the community to help convert its nebulous problems into a coherent and identifiable topic for collective investigation.

Researchers develop an informed and critical view of the daily realities surrounding issues before starting the research project. The context so identified is important as it explains the gravity of the problematic situation from the community's point of view. During this phase, the researcher explains the purpose of the project and begins to solicit help from key individuals in the community who would play an active role in the execution of the project. The researcher acts as a discussion organizer and facilitator and as a technical resource person. Together with a collaborating organization—such as a community development agency, social service agency or community health clinic—the researcher contacts members of the community, activates their interest in the problem to be dealt with by action-driven research and helps organize community meetings for discussion of relevant issues. This situation is heavily contingent on the interpersonal and political skills of the researcher as an organizer. Unlike traditional field research, PAR puts community

members in the role of active researchers—not merely passive information providers—even in the pre-data-gathering phase.

A dialogic approach requires that both the researcher and the participants maintain healthy mutual relationships. This manner of partnership is not easily forged, especially with people who have been victims of a dominating structure. Entrenched submissive attitudes and negative self-images reinforce subordination to outside researchers. Researchers too may find it difficult to relinquish the role of experts and may end up consciously or subconsciously imposing their own ideas. To counter these tendencies, all research stakeholders must actively engage in self-reflection. They consciously need to examine the sources of social power in their lives and how these sources could end up biasing their research. In the PAR world view, the characteristics of participants' position are relevant constituents of their knowledge.

Methodology

PAR combines research and action through a cyclic or spiral process which alternates between action and critical reflection. It lays emphasis on authenticity rather than on the scientific validity of the information. Therefore, statistically significant and generalizable conclusions are generally avoided.

PAR involves a flexible set of techniques. It combines popular education methods—such as diagrams and visual aids—which must be creative, expressive and culturally relevant. The use of 'problem-posing' dialogues encourages critical analysis through group discussion. Diagramming and visual techniques, used extensively in Participatory Rural Appraisal, aim to understand and cross-check a community's lived experience to assess, identify, prioritize and evaluate projects. PAR excludes all techniques of experimental studies in which experimental subjects are kept ignorant of the purpose of the study. Field observation; archival and library research; historical investigations using personal history documents, narratives and storytelling and questionnaires and interviews are the most extensively used field techniques.

PAR's methodology is distinctive in that it encourages researchers to ignore discipline-bound methodologies and to be flexible. They try multiple data collection methods and instruments, develop unconventional methods and apply unconventional criteria for determining the appropriateness of those methods. Methods are chosen or developed because they can potentially draw out useful knowledge and because they invite the involvement of all stakeholders. Since PAR places a premium on the experiential knowledge of community members, approaches like informal interviews or

open-ended questions might be chosen over more structured researcher-controlled data collection methods.

PAR often requires innovative, user-friendly approaches to the dissemination of knowledge as well. Community organizations expect tangible results that they can put to use. It follows that research findings need to be presented in a form accessible to the community, organizations, politicians, agency personnel and any others who might make use of the research findings. This requires that researchers demystify the language used in research reports. It also calls for the use of innovative, creative methods of describing and reporting results that may not involve writing at all, for instance, video, art, community theatre or quilting.

As advocacy for change is an important objective of PAR, it also needs to garner support for local issues at the highest decision-making level. To create such a multiplier effect, PAR involves visits, workshops, seminars, multi-stakeholder meetings and academic journals in which microlevel experiences and insights are shared with a view to sensitize those monopolizing authority and knowledge resources.

PAR in Mobilizing Community Knowledge: A Case Study

Jamtara, a district in the Indian state of Jharkhand, has a high incidence of child labour engaged in hazardous occupations such as bidi (indigenous cigar) rolling, brick kilns and rag picking. The parents are mostly tribal, illiterate and poor and themselves face severe livelihood constraints. As a step towards eliminating child labour, the government in 1996 established schools to provide non-formal education (NFE) to working children. The NFE schools aimed to educate working children up to Class 3 and then to transfer them into mainstream, government-run primary schools. The NFE schools gradually became defunct due to the apathy of government functionaries and the high dropout rates.

Participatory Research in Asia (PRIA), along with a Jharkhand-based NGO, Lok Jagriti Kendra, initiated community monitoring of a service delivery project run by the state government in 2000 which sought to provide NFE to working children in Jamtara. This action-oriented development-monitoring process was based on the assumption that engaging the community to monitor the functioning of NFE schools would establish accountability, responsiveness and transparency in the governance of social development projects, while giving the community a measure of control over their immediate situation.

An exploratory study of NFE schools helped gain insight into the actual working of the schools and in understanding the concerns of various stakeholders,

such as parents, local civil society activists and school teachers. Consultations with different stakeholders revealed that participation of parents as stakeholders was practically non-existent as they were unaware even of the project's basic provisions.

Meetings with many parents followed at the village level. Through a sustained process of reflection, articulation and action, the parents of working children from three schools in Jamtara came forward to form parents' committees that would monitor the quality of education in NFE schools. PRIA facilitated workshops to build the capacity of the parents' committee. The committee members eventually decided on three indicators upon which they would measure the school's functioning: (1) the presence or absence of the school teacher, (2) the serving of the midday meal and (3) routine health check-ups for the children.

Since the parents were illiterate, they devised worksheets to record the data using pictures, drawings and graphics to depict the three indicators. They decided the modalities of monitoring and the roles and responsibilities of the monitors. Data was collected three to four times a month. The committee monitored the first two indicators for 4–5 days a month and the health check-ups once a month. Armed with reliable data that they themselves had collected, the parents' committee organized structured meetings with concerned government authorities, circle officers and medical officers to apprise them of the facts and petition them for redress or corrective action. For instance, slackness on the part of doctors in conducting routine medical check-ups of students, vacancies in teachers' posts, need for repair in schools and lack of sports equipment in the schools were some of the issues highlighted. The community also put up a number of demands which they felt had a bearing on the larger goal of eliminating child labour, such as extending the benefits of various government schemes, including small-income opportunities, to parents; ensuring timely disbursement of stipends and salaries and timely supply of school uniforms, books, writing material, sports goods and other inputs and compliance on regular health check-ups of children.

After a series of meetings and workshops, the government authorities initiated several actions to revive the schools and encouraged the parents to apply for loans under programmes which supported poor and asset-less people so that their economic condition could improve, potentially freeing their children from the need to earn.

The community stakeholders were involved in the multivalent processes of knowledge (research), reflection, learning and action. The process of research gave them self-confidence and control in decision-making. Capacity building enhanced their knowledge base. Participatory community monitoring enhanced their practice of citizenship. Community monitoring eventually

made government agencies considerably more accountable and transparent. This small step went a long way in widening and deepening the democratic process at the most basic level.

Though external agencies such as PRIA and Lok Jagriti Kendra were responsible for mobilizing at the initial stages, over a period of time, this control gradually moved entirely into the hands of the parents committee and the local community.

Challenges

Lack of clarity over the rationale of participation in the research process presents challenges in conducting PAR. Participation is overly emphasized in the data collection or analysis. PAR is used to manipulate community participation to fulfil the predetermined agenda of research. The community collaborate in data gathering, while setting the agenda of research, control and ownership of results through joint analysis and development of action plans and decision-making are out of bounds.

PAR requires time and sensitivity on the part of the researcher to understand community needs. With divergent perspectives, values and abilities among community members, consensus for determining the agenda of action for change and the time frame anticipated for the change might be difficult. Competing, contested and changing versions of community needs or values often influence agendas and provide means for enacting solutions for some while blocking others. A community may become sceptical about investing its time and energy, particularly when little is offered in terms of direct benefits.

PAR involves community members in the research not only as subjects but also as co-researchers. Community organizing appears to be a necessary step prior to the PAR process. This raises questions about the extent to which the external professional researcher should engage in community organizing to develop the community's capacity to define its own research question or take the lead in developing research questions. Researchers may not be trained for community-organizing strategies to jointly develop research questions with the communities. Involving community members in developing the research questions may risk having to work indefinitely on community organizing. Some communities may never reach the point at which they are comfortable defining a research question.

PAR Ethics in Mobilizing Community Knowledge

Given the principles, processes and challenges of PAR, the ethics of PAR can be classified within the following criteria.

The element of active citizenship should be woven into PAR projects. Simply providing space for dialogue is not sufficient. There must be an opportunity for local communities to have some control over their immediate situation and to participate in making changes at the ground level and in the governance process.

PAR should be used for conscientization—it should aim at bridging the gaps between different forms of knowledge, such as the popular and the technical. Multidisciplinary and mixed-methods approaches to issues should be supported.

Commodification of PAR as a rhetoric or method for knowledge generation should be resisted. PAR needs to appreciate and recognize the ideas and expectations of the community at hand. Collaborations between community members, practitioners, policy institutions and other stakeholders, such as the academic and corporate sectors, should be promoted for the purpose of mobilizing community knowledge. Networks between these institutions should be revitalized and sustained through constant dialogue, action and research.

If empowerment of the community through knowledge is to be pursued, then the proponents of PAR should emphasize that transparency and accountability of research are important issues in the generation and use of knowledge.

PARTICIPATORY BUDGETING

Budget preparation takes place in every household, organization, development programme and government to provide for identified needs with the available resources for a specific period. Resources generated from tax payers or grants received from a donor are allocated in different ways, called budget lines or budget items, to be spent in a particular manner. The conventional budget preparation is done by those who are in control of the resources, though the impact of the spending will be on the citizens or beneficiaries. When the citizens or those who will be affected by the spending of the budget are involved in the process of budget making, it becomes participatory. In conventional budgeting, the citizens, who may be affected by the budget, are not expected to provide suggestions, or their feedback is not heard.

Effective participatory budgeting is the process where the citizens can exercise control over the resources, know and demand their rights, explore opportunities and work towards equity and justice. Participatory budgeting is a step towards making governance more democratic, accountable and transparent. Participatory budget-making processes are also empowering to citizens for political and social transformation by bringing in the voice of the unheard into centrality and developing collective leadership for planning, implementation and monitoring.

Prerequisites of Participation in Budgets

The language of budgeting is highly technical and professional. Therefore, one of the conditions is that

the budget-making agencies make it simple so that ordinary citizens can understand the processes, available resources and technical terms clearly. The second important condition is that the information should be disseminated in the language spoken and understood by the local people. The third condition is that the process of budget planning should have built-in components of participation so that participation in budget making gets institutionalized. A vibrant civil society and the media also add value in determining new ways of participation and demonstrating models of empowered citizenry.

Stages of Participation in Budget Process

In the pre-budget and budget formulation stage, the key policymakers engage with the communities or different stakeholder groups so that the appropriate needs and priorities can be articulated and considered. Civil society organizations often bring forth assessments of the previous budget to inform the parliamentarians or relevant policymakers of the mismatch of expenditure and budgets based on the articulated needs or guidelines. The media also play an important role in highlighting the relevant issues and generating debate.

During the budget implementation stage, parliament or policymaking institutions through mechanisms like committees or commissions provide oversight function. Civil society organizations support the implementation of budgets as well as provide a grass-roots perspective on the implementation process of the budget. The budget monitoring and evaluation highlight whether the resources spent are in line with the budget. They also highlight whether the expenditure is for the intended purposes.

Experiences of Participatory Budgeting

There are many countries where participatory budgeting has been institutionalized, such as South Africa and Uganda, where it is enshrined in the constitution. Porto Alegre, a town in Brazil, is a good example of participatory planning and budgeting. The municipality organizes a sustained, year-long mobilization of participants and elected representatives through meetings and deliberations on budgets. The resources are clearly allocated for different zones. There is a principle of positive discrimination based on the quality-of-life index. The priorities, policies and resources are negotiated in open meetings. The elected representatives vote on the final projects, and the council approves the budget. Neighbourhood committees are set up to monitor the performance.

In Kenya, pre-budget hearings are organized. In Kerala, one of the states in India, people planning is

exercised at the local elected government, called a village panchayat. Each panchayat is given a flexible budget to plan according to key guiding principles. In a large-scale programme on the right to employment implemented by the Government of India, every village prepares a labour budget to determine the number of days of employment required in a year by families demanding employment. This becomes a basis for planning the budget for the activities to be initiated for providing labour employment by construction of civil structures in the village. The budget is planned and approved by the village council.

Knowledge Production and Action Research

A participatory budget encourages ownership by those most affected by the budget allocations. Therefore, the citizens, who are affected by the service or as taxpayers, decide to generate data on the problems and analyze their own situation. Local solutions are identified, and technical experts adapt solutions to the best interests of the people and for efficient use of the available resources. This negotiation between the community and the experts generates new knowledge and promotes action research. It also promotes participatory governance and strengthens democracy as citizens demand accountability from their elected leaders and policymakers. Active engagement of citizens in planning and budgeting, based on local knowledge generation, leads to action research to identify solutions for effective implementation and further planning. Repeated cycles of participatory budgeting lead to dynamic knowledge production and action that is controlled by the people as responsible citizens.

The process of getting the participation of the poor or the marginalized in the budget process is time, resource and skill intensive. Often, the authorities do not have the luxury of time, and therefore, the quality of participation is compromised. Sometimes, even after participation, the planned budget or its implementation does not happen according to expectation. Without serious commitment from policymakers, this becomes a frustrating experience for the participants.

PARTICIPATORY DESIGN PROGRAMMING

Participatory design is an attitude about a force for change in the creation and management of environments for people. Its strength lies in being a movement that cuts across traditional professional boundaries and cultures. Its roots lie in the ideals of a participatory democracy where collective decision-making is highly decentralized throughout all sectors of society, so that all individuals learn participatory skills and can effectively participate in various ways in the making of all decisions that affect them. Often, the term *participation* is modified with different descriptors, resulting in terms such as *community participation*, *citizen participation* and *public participation*.

Today, participatory design processes are being applied to urban design, planning and geography as well as to the fields of industrial and information technology. Research findings suggest that positive outcomes are associated with solutions being informed by users' tacit knowledge. More recently, another factor has been suggested as being partly responsible for favourable participatory design outcomes, which is described as collective intelligence. Tom Atlee, in his book *The Tao of Democracy*, describes collective intelligence as a shared insight that comes about through the process of group interaction, particularly where the outcome is more insightful and powerful than the sum of individual perspectives. When people align their individual intelligences in shared undertakings, instead of using their intelligence to undermine each other in pursuit of individual status, they are much more able to generate collective intelligence.

Three main issues have dominated the discourse in participatory design literature: (1) the politics of design, (2) the nature of participation and (3) the tools, techniques and methods for carrying out design and planning projects.

Public participation builds on classic democratic theory that those citizens who are affected by decisions should have a say in decisions that affect their lives because they will become better citizens. Participation is effective when the task is conceptualized in terms of what is to be accomplished when the need is acknowledged to involve citizens. And it is often the physical and environmental projects that citizens see directly affecting their lives. To create a condition in which

people can act on their own environmental needs, in which they can make the distinction between the experts' technical and aesthetic judgement, requires a change in the consciousness of both community members and professionals.

Citizen participation in community decision-making can be traced as far back as Plato's *Republic*. Plato's concepts of freedom of speech, assembly, voting and equal representation have evolved through the years to form the basis upon which the USA was established. Some historians support the notion that Americans have always wanted to be part of decisions affecting their lives. Freedom and the right to make decisions on the early American frontier was the shaping force in grass-roots democracy—in other words, people's right to participate. As many frontier villages grew in population, it became increasingly difficult for every citizen to actively participate in all community decisions. To fill the void in the decision-making process, people began to delegate their involvement to a representative, which grew into the system of selecting officials by public elections and increased the number of volunteer associations and organizations. Although public participation can be approached and defined in many different ways, this discussion is concerned with participation aimed at issues involving community decision-making.

In 1915, Patrick Geddes wrote *Cities in Evolution*, an essay on the growth of cities, in which he emphasized the preservation of historical traditions, the involvement of the people in their own betterment and the rediscovery of past traditions of city building. His legacy includes a tried and tested method—that of a regional report or survey—which was intended to gain an overall perspective of an area's social ecology. This approach identified and assessed the physical and social factors that may be considered to contribute to human health—such as housing, employment, air quality, water supply, the availability of gardens or natural areas and the nature of cultural identity. Geddes stressed the need to identify the links between the different factors, and where deficiencies exist, he would search for appropriate solutions. These would often require political, social and physical intervention. The current emphasis on evidence-based policy appears to reflect this strategic, interdisciplinary and integrative approach to planning.

Participatory design is commonly associated with the idea of involving local people in social development. The most important influences came from the Third World community development movement of the 1950s and 1960s, Western social work and community radicalism. The plans of many developing countries emphasized co-operative and communitarian forms of social and economic organization, stressing the values

of self-help and self-sufficiency, advocating that the poor and the oppressed should be mobilized to promote social and economic progress. Current community participation theory suggests that politicians and bureaucrats have exploited ordinary people and that they have been excluded from the community development process. The leading community participation proponents are found in international agencies such as the United Nations, the World Health Organization and UNICEF (the United Nations Children's Fund). The emergence of community participation theory as an approach to social development is an outgrowth of the United Nations' popular participation programme that required the creation of opportunities for all people to be politically involved and share in the development process.

In her 1969 article 'A Ladder of Citizen Participation', Sherry Arnstein contends that citizen participation is citizen power but that there is a critical difference between going through the empty ritual of participation and having the real power needed to affect the outcome of the process. The fundamental point is that participation without redistribution of power is an empty and frustrating process for the powerless. In order to assess the types of participation and non-participation, Arnstein suggested a typology of eight levels of participation using a ladder technique.

The bottom rungs of the ladder are (1) manipulation and (2) therapy. These two rungs describe levels of 'non-participation' that have been contrived by some to substitute for genuine participation. The next three rungs, (3) informing, (4) consultation and (5) placation, progress to levels of 'tokenism' that allow citizens to hear and to have a voice but continue to retain for the power holders the right to decide. Citizens can then enter into a (6) partnership that enables them to negotiate and engage in trade-offs with traditional power holders. At the topmost rungs, (7) delegated power and (8) citizen control, citizens obtain the majority of decision-making power. This categorization of the various types of people's involvement clarifies the distinction between non-participation and citizen power and a method to identify the motivation behind participatory projects.

The activity of community participation is based on the principle that the environment works better if citizens are active and involved in its creation and management instead of being treated as passive consumers. The development of a community's potential through collaborative problem-solving is described by social scientists as Participatory Action Research, where citizens are empowered to effect social change by controlling the knowledge produced by participation. Community participation has a broad value to community life. For example, it does the following:

- *Engages the public:* In a general sense, the purpose of citizen participation is to inform the public, get the public's reactions regarding the proposed actions or policies and engage in problem-solving to come up with the best solutions for everyone.
- *Builds trust:* What adds legitimacy to a decision is not only the substance of the decision but also the perception that the process by which the decision was made was fair, open and democratic. This is true, even if some individuals or groups do not agree with the final decision.
- *Makes better decisions:* History shows that better public decisions happen when the public is involved in the decision-making process. People have more ownership for the programme's success if they have had a part in creating it. They also hold a key element that only comes from their experience. Decision-makers need the voice of experience to line up with the facts and figures produced by studies.

Participation means different things to different people depending on the issue, its timing and the political setting in which it takes place. The planning that accompanies the development of any participation programme should first include a determination of objectives, such as deciding whether it is to generate ideas, identify attitudes, disseminate information or review a proposal. Planning for participation requires that participation methods be matched to the objectives and the appropriate method selected.

The list of possible participation objectives will differ from time to time and from issue to issue. Once the objectives of community participation are stated, it becomes clear that participation is perceived according to the type of issue and the people involved. If differences in perception and expectations are not identified at the outset, and realistic objectives are not made clear, the expectations of those involved in the participation programme will not have been met, and they will become disenchanted. Integral to the concept of participatory design is that of participatory programming, which is a process of identifying people's specific needs through a variety of engagement techniques.

Although it is critical to examine goals and objectives in planning for participation, there are various techniques that are available, each of which performs different functions. In the past several decades, there have been numerous efforts to accumulate knowledge about various participation techniques, as well as the function that these techniques perform. Community surveys, review boards, advisory boards, task forces, neighbourhood and community meetings, public hearings,

public information programmes and interactive cable TV have all been used with varying degrees of success, depending on the effectiveness of the participation plan. Because community participation is a complex concept, it requires considerable thought to prepare an effective participation programme. At the same time, designers and planners to acquire information have effectively used field techniques such as questionnaires, interviewing, focus groups and group mapping. In general, many of the techniques facilitate citizens' awareness to environmental situations and help activate their creative thinking. Some of these techniques have become standard methods used in participatory processes, such as the use of interactive group decision-making techniques in workshops. Face-to-face interaction, often referred to as a workshop, characterizes all group methods.

Although there are numerous interaction methods, including focus groups and simulation gaming, the *charrette* process is the most common. Focus groups usually consist of 6–10 carefully selected people, with a facilitator who guides the discussion to relevant issues. Gaming is a participatory approach to problem-solving that engages a real-life situation compressed in time so that the essential characteristics of the problem are open to examination. This technique permits learning about the process of change in a dynamic environment requiring periodic decisions. Essentially, a complex problem is identified, its essence is abstracted and the end result is a process referred to as simulation. A charrette, however, is an intensive participatory process lasting several days or longer, depending on the complexity of the problem. This is a process that convenes interest groups in a series of interactive meetings aimed at solving particular problems. Phases of the charrette process may include workshops or working sessions that engage participants in the development of ideas, recommendations and decisions. This is a hands-on approach whereby professionals and citizens work together with plans, photographs and/or models to explore alternatives. *Charrette* is the French word for 'cart' or 'chariot', whereby architecture students would be working on projects until a deadline, when a charrette would be wheeled among the students to pick up their work for review while they were still working *en charrette*, in the cart.

The development of a single participatory method has not been the aim of researchers and practitioners in design and planning. However, some groups have organized their practice into an ensemble of tools and techniques characterized by the charrette process.

When faced with complex problems and diverse interests, collaborative decision-making embraces face-to-face interaction and encourages creativity, open communication, broad participation and agreement. Designing a clear, well-managed collaborative

process can lead to agreement where all participants are likely to receive wide community support during implementation. This involvement should give the participants full inclusion in designing, organizing and implementing activities and workshops in order to create consensus, ownership and action in support of environmental change in specific areas. It should include people and groups rather than exclude any individuals.

PARTICIPATORY DISASTER MANAGEMENT

All civilizations, ancient and current, have known natural disasters, be it in the form of earthquakes, floods, landslides, cyclones, wildfires, avalanches or tsunamis, to name a few. Country after country suffers loss of human lives and damage to property, leading to many adverse effects on the economy and society. Between 1994 and 2003, over 3,000 disasters were recorded, affecting on an average 255 million people and claiming an average 58,000 lives each year. Current statistical trends and scientific evidence of climate change assert that these events can only increase in both frequency and intensity in the coming years. Furthermore, the United Nations estimates that by 2025 half of the world's population will live in areas subject to major storms and excessive flooding. If the trend continues, it is estimated that by 2050 natural disasters will have a global cost of over 300 billion dollars a year.

Types of Disasters

Natural Disasters

These disasters include floods, hurricanes, earthquakes and volcano eruptions that can have immediate impacts on human health, as well as secondary impacts causing further death and suffering from floods causing landslides, earthquakes resulting in fires, tsunamis causing widespread flooding and typhoons sinking ferries.

Environmental Emergencies

These emergencies include technological or industrial accidents, usually involving hazardous material, and they occur where these materials are produced, used or transported. Large forest fires are generally included in this definition because they tend to be caused by humans.

Complex Emergencies

These emergencies involve a breakdown of authority, looting and attacks on strategic installations. Complex emergencies include conflict situations and war.

Pandemic Emergencies

These emergencies involve a sudden onset of a contagious disease that not only affects health but also disrupt services and businesses, bringing economic and social costs.

Disaster Mitigation

Disasters have the potential to interrupt essential services, such as the provision of health care, electricity, water, sewage or garbage removal, transportation and communications. The interruption can seriously affect the health and social and economic networks of local communities and countries. Disasters have a major and long-lasting impact on people, long after the immediate effect has been mitigated. Poorly planned relief activities can have a significant negative impact on the disaster victims in terms of exclusion, appropriateness of materials with reference to needs and timeliness of the support. Disasters contribute in entrenching poverty in already impoverished countries. In the absence of risk transfer mechanisms and social protection, it is usually the poor and the underprivileged who are the worst affected. It is understood that development cannot be sustainable unless disaster mitigation is built into the development process. Investments in disaster mitigation are more cost-effective than expenditure on relief and rehabilitation. Actions on disaster prevention and mitigation contribute to lasting improvement in the creation of safety standards and are essential for sustainable development.

Disaster Response

Disaster response in the form of early warning, evacuation, search and rescue, relief and rehabilitation is a component of disaster management. These are response-related actions in a post-disaster situation. Prevention, mitigation and preparedness are part of development interventions which help achieve vulnerability reduction and build capacity for effective response.

A hazard, leading to widespread human, material, economic or environmental losses, disrupts the functioning of a community when people are not able to withstand the impact because of a vulnerability. Vulnerabilities can be categorized into physical and socio-economic vulnerabilities. Physical vulnerability includes notions of elements that may be damaged or destroyed by natural hazards. It is based on the physical conditions, such as buildings and infrastructure, and their proximity to the hazard. It also relates to the technical capability of buildings and structures to resist the forces acting upon them during a hazard event. In disaster response with regard to shelter reconstruction, 'owner-driven reconstruction' is the first step to make reconstruction participatory. Shelter reconstruction approaches are often driven by outside agencies, materials and technology which people are not familiar with. When the people are enabled to make their own choices in terms of design and material, along with additional knowledge of the quality of material and safety standards, the communities feel empowered.

Socio-economic vulnerability refers to the degree to which a population is affected by a hazard in relation to socio-economic conditions. For example, people who are poor and live in at-risk regions do not have the resources to construct strong, secure houses. They are generally vulnerable, and their shelters are damaged or destroyed whenever there is a strong wind or cyclone. Because of their poverty, they are also not able to rebuild their houses. It is often seen that in a post-disaster situation the support to rebuild houses is determined in terms of replacement cost. The support for reconstruction needs to be at such a level that the community improves socio-economic conditions, which means improving habitats, working conditions and infrastructure to cope with future disaster situations.

Capacity Building and Action Research

Disaster management in the post-disaster situation can fall to the community, or more often, an external disaster response is required when the local community is unable to respond. However, it is important to build capacity in terms of resources, skills, technology and management at household and community levels to enable people to cope with, withstand, prepare for, prevent, mitigate or quickly recover from a disaster. Capacity building to reduce the impact of the hazard can be in terms of structural mitigation measures like the construction of safe houses, growing mangroves as wind breaks or building water channels, or it can be in terms of non-structural measures such as mock evacuation drills, improved safety standards and building by-laws and mason training.

People's capacity is often addressed in a techno-managerial manner. Offering only a few rounds of training or bringing in external consultants to implement universal safety standards will not necessarily build disaster resilience. However, when the community is involved in assessing needs, deciding on themes for training and planning the process for the implementation of standards, the community is empowered, which leads to sustainable capacity development. For example, outside consultants may think that planning and safety standards are too technical for the community to comprehend. However, whereas engineers may only consider standard materials, the community can suggest diverse local material in diverse contexts. Or most communities are against the idea of relocation and will continue to build and rebuild in disaster-affected areas. Planners can contribute technical knowledge to improve on the community's traditional and in situ planning. Therefore, community-based Participatory Action Research opens up diverse opportunities for disaster management.

It is increasingly being realized that communities have local knowledge to address hazard events. Mary B. Andersson and Peter J. Woodrow argue that the post-emergency aid assistance has to be designed so that it supports local development and does not create external dependency. In different post-disaster scenarios, it has been observed that where people are organized, they recover from the disasters through their own efforts better than those who are not organized. For example, in a post-earthquake scenario where the houses were fully damaged, the community had two options for housing recovery: (1) residents were provided with prefabricated materials like tents for transit shelter or (2) they were mobilized to salvage the housing material and rebuild their transit shelters with minimum external support. With the second option, people recovered better post-disaster without any adverse impact on their health and social relationships.

Participatory Disaster Risk Assessment

While relying on the community's capacity is a key principle of participatory disaster management, the role of external support should not be negated. Disaster risk reduction cannot be effective if it is the sole responsibility of disaster managers; it needs to strengthen local capacity and action as well. Participatory disaster management is ultimately aimed at building resilient communities. As part of capacity building, local organizations must analyze, plan and implement activities related to disaster risk reduction.

In order to roll out an effective post-disaster response, the community needs to train up several task forces that address early-warning systems, evacuation,

search and rescue, first aid, management of camps in the evacuation spots, water and sanitation, temporary shelter, damage assessment and so on. These task forces need to initiate and complete participatory disaster risk assessments under normal circumstances. During these assessments, the nature and behaviour of different hazards witnessed by the community in the previous several years are analyzed. The assessment looks at the warning signs, frequency, magnitude and force of the hazard. It also looks at the different elements that were affected by the hazard.

In the risk analysis process, the community examines the local capacity for prevention, response and mitigation. Communities have many capacities which they need to be aware of. Based on the hazard, vulnerability and capacity assessment, the community can map out 'elements at risk' to different hazard events in different intensities. The community will find it liberating and empowering if the exercise is conducted in a truly participatory fashion using appropriate tools and techniques.

After the disaster risk analysis has been completed, the community needs to develop a disaster management action plan. For example, development programmes can be used to build raised mud platforms as rescue places for people and cattle in the event of a flood. To reduce the impact of a cyclone, the community can plant mangroves in partnership with the forestry department. In some places, the poor communities make contingency plans to sell their poultry, goats and sheep before the onset of flooding as the animals are too difficult to take care of during a crisis and so they can avoid distress sales.

Conclusion

In the past decade, there has been a major shift in the approach to disaster management. Instead of just responding to hazard events, the approach has been risk reduction through hazard prevention, mitigation and vulnerability reduction by building individual and community capacity. The new approach espouses the building of community resilience. The Hyogo Framework of Action declared at the World Conference on Disaster Reduction in Kobe, Japan, 2005, and the Hyogo Framework of Action-II, Geneva, put emphasis on capacity building in the local community. It has been globally acknowledged that until the community is empowered to address disaster risk reduction measures, the national policy and institutions cannot make much contribution.

PARTICIPATORY EVALUATION

Participatory evaluation (PE) encompasses evaluation approaches actively involving stakeholders in planning and implementing evaluation studies, as well as using evaluation results. PE approaches are characterized by their underlying motivations: (a) a pragmatic interest in making evaluation meaningful and useful, (b) a social constructivist epistemology and/or (c) a political interest in social justice and fairness.

All evaluation approaches involve stakeholders; this is a sine qua non of evaluation. Stakeholder involvement takes a particular form in PE—it must be broad and fundamental to decisions made in the evaluation process, including defining evaluation questions, deciding what methods best answer those questions, deciding from whom to collect data, analyzing data and disseminating and using the evaluation results. Additionally, PE employs many methodological approaches even though qualitative methodologies are common.

Action research, especially Participatory Action Research (PAR), and PE share many attributes and have some common roots. Both seek involvement of less powerful stakeholders in the inquiry process, emphasize the process of participation, acknowledge the validity of popular knowledge and are committed to action as a result of the inquiry. PAR has its roots in community and international development and, more recently, feminist studies. Some PE shares these roots, but others respond to the evaluation research literature of the late 1970s and early 1980s, showing that evaluation results do not speak for themselves and more engaged stakeholders will increase the likelihood that evaluation findings are meaningful and actionable. The similarities between PAR and PE are most obvious in transformative PE, which will be described in more detail below.

What follows is a description of the primary types of PE with illustrative examples, and the entry concludes with a description of the advantages and challenges of PE.

Defining PE

PE is an umbrella term covering a range of notions of participation. In general, all PE involves a broad

and diverse range of programme stakeholders (staff, service recipients, donors and communities), but typically, it emphasizes the participation of those stakeholders less likely to have decision-making authority (e.g. service recipients and staff). PE assumes that these stakeholders will be actively involved in planning, executing and using the evaluation. While evaluators play different roles (methodological expert, coach, mentor or facilitator), ultimately responsibility for the evaluation devolves to the programme stakeholders.

The US Agency for International Development in 2011 summarized PE's guiding principles as follows:

- *Stakeholder ownership*: Create structures and processes to include those most frequently powerless or voiceless in programme design and implementation. Participation honours human contributions and cultural knowledge.
- *Negotiation*: Participants collaboratively decide on the evaluation focus, how it should be conducted, how findings will be used and what action will result. Often the process requires addressing different points of view and conflicts.
- *Diversity of views*: Perspectives of a broad range of stakeholders are sought, and those with the most power allow the participation of those with the least power.
- *Learning*: Stakeholders learn together to take corrective actions and improve programmes.
- *Flexible of design*: Uses diverse methodologies that capitalize on the resources, needs and skills of participants and generate empirical findings.
- *Facilitation*: Stakeholders conduct the evaluation; however, one or more outside experts may serve as facilitators in supporting roles, such as mentor, trainer, group processor, negotiator and/or methodologist.

PE can be a collaboration between an evaluator and programme stakeholders, or programme stakeholders might assume responsibility for the evaluation. In the collaborative scenario, evaluators and stakeholders work together in identifying the evaluation focus, questions and data collection, but the evaluator has responsibility for the execution and quality control of the evaluation process. When programme stakeholders assume responsibility for the evaluation, they call on evaluators to lend technical expertise if and as needed. PE falls within one of three types. J. Bradley Cousins and Jill Anne Whitmore categorized PE as practical PE (P-PE) or transformative PE (T-PE), and within international development agencies, participatory monitoring and evaluation (PME) has emerged. These distinctions are explored in more detail below.

Practical PE

P-PE reflects evaluators' dissatisfaction with the lack of use of evaluation findings and is a decidedly North American development. It is a pragmatic response. The increased emphasis on stakeholder engagement in evaluation processes is a theme in much of the evaluation literature from the mid-1980s well into the 1990s. Increasing stakeholder involvement and creating more person-to-person connections in the evaluation process is key to increasing the relevance and ownership of the evaluation and, in turn, increasing evaluation's utility.

P-PE reflects significant stakeholder engagement in focusing the evaluation, but typically, evaluators retain control of the evaluation process and have the technical and methodological expertise to conduct the evaluation. P-PE makes sense when organizational contexts neither allow nor encourage stakeholders to make decisions and when the context does not include deeply disenfranchised or oppressed stakeholder groups. The success of P-PE is enhanced when there is relatively high agreement on issues (and lack of conflict) and when there is a core of organizational practitioners willing to commit to the process.

Illustrating P-PE

Imagine an evaluation of a school within a school—one that focuses on students talented in math and science. The director of the school hires an evaluator to facilitate a PE since she wants all of the school's constituents to be involved. There are relatively few conflicts surrounding the school—the community agrees that it is a good programme, students like it and parents seem happy, but there is still a desire to improve the school if possible. A committee with representatives of stakeholder groups (school administrators, teachers, students and parents) works with the evaluator in identifying issues to explore (should the programme focus on enrichment or acceleration), how data should be collected (surveys are familiar to the stakeholders) and from whom (teachers who are not in the programme; former students—current students are interested in knowing what they think) and how the results will be used (curriculum changes, recruitment, etc.). With limited resources, high motivation on the part of the director and teachers and stakeholders' willingness to participate, this is a reasonable scenario for P-PE, contributing to specific programme improvements.

Transformative PE

In contrast, T-PE is informed by different issues, especially the empowerment of programme stakeholders and the potential for any inquiry, including evaluation, to be a democratizing force. T-PE, like

PAR, is rooted more in Latin American and developing countries around the world, and the work of Paulo Freire is key to its foundational orientation. T-PE fosters empowerment, especially of those least likely to have a voice, through participation in the evaluation process and using evaluation for influencing social change.

The historical antecedents for T-PE suggest that attention to power issues is a key feature. T-PE assumes that within any organizational, community or programmatic context, power is differentially distributed and some stakeholders have less voice and control over actions and circumstances that make a difference to the quality of their lives. This is a concern with social justice and fairness. T-PE may rely on a democratizing framework in the vein of John Dewey, one that sees participation as key to emancipation, or on a revolutionary framework in the vein of Paulo Freire or Karl Marx, one that sees resistance as key.

Illustrating T-PE

Imagine an evaluation of an after-school programme for inner-city teens sponsored by a local museum. The programme and museum staff are mostly White; all of the teens are African American. The staff and the programme intentions are good—they want to give the teens a safe, rewarding place to be and to provide support to learn job skills. The teens' experiences are, however, not so rewarding—they are assigned menial tasks and are required to participate in group-counselling sessions. The evaluators work with all stakeholders to illuminate different perceptions and experiences within the programme, confronting defensiveness from the staff and frustration from the teens. In the process, the voice of the teens is highlighted, and opportunities for greater teen input in choosing helpful and meaningful work tasks and activities are created. The evaluation results in better communication among stakeholders, an overall stronger voice for teens and programme experiences that empower rather than patronize the teens.

Participatory Monitoring and Evaluation

P-PE and T-PE are usually episodic, evaluating a given programme, initiative or policy, and are time delimited. PME, however, conceptualizes evaluation as ongoing, an evolving process of question asking, data collection and action. Formal evaluations do arise as a result of PME, but it is first and foremost attentive to the ongoing monitoring of programme activities. A key feature of PME is the use of rapid appraisal techniques to identify when quick corrective action is required. Rapid appraisal techniques allow for quick, systematic collection of data and might include mini surveys, exit

polling, community mapping, focus groups, participant observation and walkabouts.

Illustrating PME

Imagine a school in Kenya that educates local Masai in tourism and prepares them to work as wild-life guides in the burgeoning ecotourism industry. The foundation funding the school is committed to its success and decides on PME that relies on local stakeholders to provide feedback for continuous improvement of the school and its initiatives. Those teaching at the school, Masai currently and previously enrolled at the school and local volunteers participate in a 2-day workshop orienting them to evaluation and building a team approach to evaluation. Monthly meetings provide an opportunity to identify questions and data to answer those questions. For example, graduates of the school feel that they did not learn enough about native flora and preservation of the grasslands, and a quick survey of current students illustrates that this remains a curricular shortcoming. A curriculum module can be added to provide better preparation on this topic.

Advantages and Challenges in Using PE

PE has advantages, but PE also faces challenges to be successful. Many of the potential advantages have been alluded to in the previous description of PE types. In summary, the potential positive outcomes include (a) increased stakeholder ownership of evaluation processes and outcomes; (b) increased likelihood that evaluation findings will be used; (c) opportunity for change, whether in a community, professional practice or policy; (d) learning of evaluation skills and (e) cost-effective evaluation when there are modest evaluation resources. In addition to these evaluation-specific advantages, PE may also create stronger communities, improve relationships within organizational and work contexts and build infrastructure for future inquiry.

Successful PE faces some challenges as well. Finding the time and generating commitment within the organization or programme are key. Recruiting, co-ordinating, educating and sustaining the interest of diverse stakeholder groups require both. This commitment may increase exponentially with greater programmatic or organizational complexity. Resource allocation may also be a challenge. Even though PE can be done with fewer real funds, it is the in-kind resources (e.g. time) that often must be reallocated to foster the participation required, in addition to the cost of employing external evaluators to facilitate the PE. And not insignificant is the probability that PE will create or surface conflict because of cultural, language, power and class differences. Having a conflict

resolution plan foreshadows and prepares for this likelihood, but conflict nonetheless will be challenging.

PARTICIPATORY GOVERNANCE

Participatory governance (sometimes called participatory democracy) refers to forms of governance in which citizens, and other non-state actors, are empowered to influence and share control in processes of public decision-making that affect their lives. In traditional systems of representative democracy, citizens frequently lack access to information, have inadequate opportunities for meaningful dialogue and negotiation with public actors and are excluded from processes of public deliberation and decision-making. Participatory governance practices seek to address these ‘democratic deficits’ by promoting citizen information, rights awareness, participation and influence. Since the early 1990s, a large number of participatory governance innovations have been introduced, in both ‘mature’ and ‘emerging democracies’ around the world. The value of participatory governance both as a means to enhanced governance and development results and as an end in itself, due to the intrinsic value of citizen participation, is now broadly acknowledged. While participatory governance promises significant potential political, social and economic benefits, experience shows that there are also important obstacles to achieving inclusive and effective citizen participation. Despite these challenges, participatory governance is a rapidly expanding phenomenon, in terms of both the

scale and coverage of participatory governance initiatives and the range of practices and approaches that continue to be developed by both civil society and state actors across the globe.

History and Development

Citizen and civil society participation has long been considered a cornerstone of good governance. Principles of participatory governance date as far back as ancient Athens and have been manifested in various forms throughout history, for example, in the systems of direct democracy that have functioned in the Swiss Cantons from the late Middle Ages.

Participatory governance re-emerged as a key theme in the early 1990s due to a number of trends. For many citizens and civil society organizations, demands for participatory governance are rooted in dissatisfaction with traditional systems of representative democracy and represent an attempt to address perceived deficits (e.g. lack of transparency, responsiveness and accountability) by applying the principles of popular participation, already well developed in social development spheres, to the governance domain. Participatory governance approaches are based on the premise that citizens have both the *right* and the *responsibility* to participate in the processes of public decision-making. The renewed interest in participatory governance approaches is also linked to developments in public administration—such as the emergence of public-private partnerships and the acknowledged need for multi-stakeholder approaches to deal with the complexities of globalizing economies and environmental challenges. Moreover, calls for participatory governance have emerged from the development aid and anti-corruption fields, where participatory governance approaches, in particular those involving citizen monitoring and oversight roles, are viewed as an important strategy for enhancing government transparency, effectiveness and accountability. Finally, the field of action research has made important contributions to the development of participatory governance practices and innovations. Participatory governance approaches emphasize the importance of ‘evidence-based’ interactions between citizens and the state. Many participatory governance practices are based on empowering citizens to use action research techniques to generate the information and data they need to engage in informed dialogue with state actors, undertake evidence-based advocacy, seek accountability from public officials and service providers, propose alternatives and negotiate change.

Key Features

While *participation* is a general term used to refer to an extremely wide range of practices, some level of

influence and *shared control*, not only *information sharing* or *consultation*, is typically required for an initiative to be considered an example of participatory governance. The goal of participatory governance is not to have every citizen participate in every decision but rather to ensure an equitable representation of different interests and societal groups, especially of disadvantaged or traditionally excluded groups, in those decisions and processes that most directly affect peoples' lives.

Participatory governance practices are typically evidence based, solution oriented and centred on direct dialogue and interaction between citizens and public authorities. The purpose is not to replace but rather to improve and complement existing democratic institutions. In many countries, civil society organizations have played a key role in enhancing citizen access to public information, supporting citizen-led research and monitoring, advocating for citizen rights and creating spaces and mechanisms for participatory governance. Participatory governance frequently involves strengthening the linkages and relationships between civil society and state actors.

The potential for participatory governance is arguably greatest at the local level, where citizens can directly engage with local authorities on issues of direct relevance to their daily lives, such as the provision of essential public services. However, as decision-making powers and resources are often concentrated at the central level, efforts to enhance citizen participation in national-level governance processes are also important.

Participatory governance practices can be initiated by citizens, civil society organizations or government actors; can be informal or institutionalized; can be undertaken independently or jointly and can occur at any and all stages throughout the governance cycle. A range of participatory practices with regard to public policies, plans, budgets, expenditures, services and oversight at the local through to national and even international levels have been tried and tested since the 1990s, many of them originating in the 'emerging' democracies of the Global South.

Examples

Policymaking

Participation in policymaking processes can occur through mechanisms such as public hearings, policy networks, legislative committees or multi-stakeholder bodies, such as the National Economic and Social Councils introduced in Ireland in the mid-1980s. Alternatively, citizens and civil society organizations independently undertake to monitor and evaluate decisions

and actions of the state, raise public awareness of priority concerns, critique government proposals or advocate for new policies or programmes. Such activities frequently involve action research. At the local level, community meetings, multi-stakeholder round tables and joint planning committees are just a few mechanisms used to involve citizen in policymaking and planning.

Public Budgets

Based on the pioneering example of Porto Alegre (Brazil), participatory budgeting is now practised in thousands of municipalities around the world. At the national level, more common examples of budget-related participatory governance practices include action research efforts to independently analyze the impact of budget allocations and expose the discrepancies between stated government policy priorities and resource allocations. South Africa has been a leader in both independent and institutionalized citizen participation in budgeting and fiscal policy processes. The International Budget Partnership plays an important role in promoting such practices worldwide.

Public Expenditures

An important element of participatory governance is for citizens to be able to hold officials accountable for how they manage public resources. Social movements in India have been innovators in using action research techniques such as social audits to track public spending and outputs at the local level, a practice that has now spread around the globe. At the national level, the Philippines was an early leader in establishing both independent and government-mandated vigilance committees to oversee processes of public procurement and spending. Public expenditure tracking surveys are another example of a specific form of action research aimed at monitoring the flow of public resources.

Public Services

Many participatory governance practices aim to enhance the accessibility and quality of public services. At the local level, these typically involve citizen participation in the development, management, monitoring or evaluation of priority services using a variety of methods, such as public feedback sessions and community-led monitoring and evaluation. At the national level, other action research methods, such as public opinion polls or citizens' report cards, are used to solicit citizen feedback, exact accountability and lobby for change. Information and communications technologies can be useful tools of participation both in sharing information and in collecting citizen feedback on service delivery. Countries like Korea, Brazil

and Mexico have introduced a variety of e-governance practices that can serve to streamline services and facilitate citizen access and participation.

Oversight

Local and national citizen oversight committees, the inclusion of citizen or civil society representatives on public boards and regulatory bodies and social contracts or municipal ordinances that require public officials to regularly report to and account to citizens are examples of participatory practices aimed at enhancing public oversight and accountability.

Key Benefits

As participatory governance practices evolve and expand, there is growing evidence of benefits in terms of *improved governance, enhanced development results* and *citizen empowerment*. Participatory practices can lead to improvements in governance by helping to make public processes more transparent, responsive and accountable. They can improve the quality and quantity of information fed into public decision-making, generate stronger awareness of citizens' needs (particularly of traditionally excluded groups) and create pressure for necessary reforms. Citizen monitoring and oversight can identify inefficiencies and bottlenecks, safeguard against corruption and ensure the rational use of resources, thus contributing to improvements in public services and enhanced outcomes in terms of development and well-being. Participation has an empowering effect on those who are involved, building their confidence and helping them speak up and take action towards fulfilling their needs. Participatory governance practices can encourage citizens to become more active in the public sphere and provide for civil society to engage more constructively and effectively with the state.

Experience shows that participatory governance can also bring direct benefits to state actors, including enhanced *legitimacy, popularity* and *stability*. Citizens' trust in public authorities grows when the government listens and responds to their concerns and when they feel that they have a say in processes of deliberation and decision-making. Enhanced legitimacy and responsiveness can, in turn, lead to greater public support for state actors. The risk of political instability and conflict is increased when citizens lack trust in public officials, when the government is perceived as unresponsive or when it fails to deliver essential services. By introducing opportunities for constructive dialogue and negotiation between citizens and the state, participatory governance can break patterns of unproductive confrontation and contribute to political stability and peace.

Key Challenges and Lessons

In addition to important benefits, there are significant challenges associated with achieving effective participatory governance. These include the following.

Nurturing Political Will

Initially, public authorities can feel threatened by participatory governance approaches, fearing a loss of power or privilege. If genuine political will is lacking, public authorities may only pay lip service to participatory approaches, and no meaningful results will be achieved. Political will can be nurtured by introducing incentives and sanctions, demonstrating the benefits of participatory governance and mobilizing public support.

Understanding and Addressing Power Relations

Participatory governance processes run the risk of being dominated by more powerful or influential stakeholders. To be meaningful, participatory governance processes must engage with and change power relationships. Explicit and constant efforts are required to guard against elite capture and to empower disadvantaged, less organized or traditionally excluded groups such as poor people, women and ethnic minorities.

Affirming Human and Civil Rights

For citizens to participate effectively in governance processes, their basic human and civil rights, such as the rights to information, association, free expression and rule of law, must be respected. In contexts where this is not the case, initial efforts must frequently focus on advocating for these rights. Participatory approaches are more likely to have an impact if they are backed up by legal guarantees of participation as a right. Some countries, such as the Philippines, Brazil and Bolivia, have adopted laws and policies acknowledging citizen participation as a democratic right.

Negotiating Mutually Agreed Terms of Engagement

While participatory governance practices are frequently initiated by either civil society actors or government actors, the impact is greatest when state and non-state actors succeed in developing joint initiatives based on a process of negotiation and mutual agreement. New forms of participatory governance challenge the status quo and can create uncertainty about how to get things done. For participatory governance to be effective, old rules and procedures need to be replaced by new, mutually agreed terms of engagement that clearly define the roles, rights and responsibilities

of the various parties and outline processes for collective deliberation and decision-making.

Developing New Capacities and Skills

Participatory governance requires new attitudes, skills and relationships on the part of both state and non-state actors. Attention must be given to strengthening the capacity of citizens, community representatives and civil society organizations, on the one hand, and public authorities, civil servants and service providers, on the other. Bringing these different actors together in joint learning events can be an excellent way to build both the skills and the relationships required for successful participatory governance.

of participatory approaches and methods which are rooted in the participation of people in the processes of sharing and learning about the issues that concern them, and in the action required to address them. PLA is a reflective practice which provides space for dialogue and for the sharing of knowledge and engages local people in joint analysis and action in a creative way. It is a facilitated process that focuses on the learning and personal transformation of participants, which often leads to broader community empowerment and mobilization. The local people involved are often those who have been marginalized and disempowered, and PLA approaches recognize the importance of analyzing and challenging the power differentials that have excluded them. PLA also aims to challenge biases, assumptions and preconceptions about knowledge, by recognizing and validating the plurality of knowledge and the different perspectives and world views.

PLA tools and approaches bring together different disciplines and contexts, such as agriculture, health, urban planning and community development. PLA methods can be used at each stage of programme and project cycles: in planning, implementation, monitoring and evaluation and for ongoing support, coaching and analysis. Continuous joint learning and critical reflection are embedded in PLA interventions. There is a diverse range of innovative PLA tools and methods which have been developed and are designed to be used in a flexible manner. This entry reviews the origins of PLA and its basic principles and methods and concludes with a discussion of some of the challenges of this form of action research.

Origins

PLA has its roots in many ancient traditions and indigenous rights movements.

Community-Based Systems of Governance

Local informal community forums, such as the Gotti, were operating in India 2,000 years ago. Community members met as equals to debate, to celebrate and to work together, and there was strong women's leadership. These forums have been revived by the indigenous communities, largely by the youth—for example, the *Adivasis* in Andhra Pradesh in 1990—as a reaction to domination by powerful elitist groups, as well as due to dissatisfaction with outside development interventions.

Indigenous Management of Common Resources

Be it pastoralists making arrangements for grazing on common rangeland, bird trappers transforming paddy fields into man-made wetlands during the non-farming

PARTICIPATORY LEARNING AND ACTION

Participatory Learning and Action (PLA) is a form of action research and an overarching term for a range

season or lines of villages from upstream to downstream constructing traditional *qanats* for transferring water underground, local people and communities have always demonstrated their innovativeness and resourcefulness in designing and managing livelihood systems appropriate to their environment, needs and resources in an equitable and sustainable way.

Indigenous Knowledge Systems

The indigenous communities, such as the Māori and Aborigine, worked together to build their collective capacity to enhance their spiritual connection to the earth and land and share their knowledge of biodiversity, food and farming systems and agroecology.

Oral History Traditions

These traditions from Africa, Latin America, Europe and Asia have been revived through participatory storytelling, Theatre for Development, community radio and participatory video.

PLA also evolved out of more recent development approaches which link theory with action, such as the following.

Rapid Rural Appraisal and Participatory Rural Appraisal. Rapid Rural Appraisal (RRA) emerged in the late 1970s as a reaction to conventional development practices such as surveys, which often portrayed an inaccurate picture of poor people's reality and were time-consuming and costly. RRA brought about a rapid growth in the development of innovative and alternative tools and methods, for example, semi-structured interviewing and mapping. RRA changed development practice and its ways of working with local people. It enabled researchers to 'extract' information from rural communities in a more interactive and effective way. RRA later became known as Participatory Rural Appraisal (PRA) as the processes of joint analysis became more intrinsic. As Robert Chambers has noted, dominant behaviour by outsiders might explain why PRA did not emerge and spread until the 1990s. It then became known more widely as PLA, as it extended its focus beyond rural development and embraced a change from appraisal to learning which moved participatory methods from an extractive process by outsiders to a sustainable-learning process involving different stakeholders as equal partners, where poor and marginalized communities examined their own issues, set their own goals and monitored their own achievements. It also emphasized the relationship linking learning to action, where programme and policy improvement which affects people's lives becomes a part of the process. So vital is the practice of reflection in this learning process that PRA has also become known as 'participatory reflection and action'.

Activist Participatory Research. Inspired by Paulo Freire and his theories of critical pedagogy, this philosophy was grounded in the empowerment of the underprivileged and oppressed and led to their political activism. This approach uses dialogue and joint research to enhance people's awareness (conscientization) and to empower them to take action, with outsiders acting as catalysts and facilitators. It recognizes and, subsequently, facilitates the emergence of the creativity and capability of poor people.

Applied Anthropology. Conventional social anthropology is mainly concerned with understanding rather than engaging. Applied anthropology recognizes and validates the diversity and richness of local people's knowledge. It also emphasizes and values the importance of attitudes, behaviour and relationships and how these change throughout a process.

Agroecosystem Analysis. Drawing on the traditions of agroecology, this holistic approach combines the analysis of systems with pattern analysis of space, time, flows and relationships, relative values and decisions.

Farmer-Led Agricultural Research. In the 1990s, farmers' participation, experimentation and innovation in agricultural research demonstrated improved outcomes and became recognized as valid and necessary.

Learning Process Approaches to Development. Korten's approach, developed in the 1980s, embraces mistakes, plans with people and links knowledge and action. It uses organizational learning to improve the effectiveness of organizations.

Principles

Despite the development of many different methods and tools, PLA approaches share some key principles which are crucial for their success:

- *Co-learning and co-analysis:* PLA is a process of co-learning and co-analysis by all the participants, including the facilitators, which also guides the development of different methods.
- *Good facilitation:* PLA processes are usually guided by facilitators who are not members of the community with whom they are interacting. The facilitator's role is to show participants how to use the tools and ensure that everyone is able to participate equitably. The tools are not participatory in themselves. The right attitudes and behaviours are key, and there should be no external or hidden agenda. The facilitator can also act as a catalyst for the local people to take action on the findings they generate.

- *Valuing multiple perspectives:* PLA is not about simplifying complexity—it seeks diversity, drawing on multiple world views, which lead to different evaluations and different actions in different contexts. Trust, rapport and mutual respect are essential for a PLA approach and, when present, can lead to productive exchanges where everyone's views and knowledge become explicit and are valued.
- *Group interaction and joint analysis:* Using PLA tools in group learning processes unravels complexities and enables us to recognize that communities are not homogeneous.
- *Context specific:* PLA approaches are flexible and can be adapted to different contexts and actors, encouraging innovation and diversity as well as creativity and spontaneity. This often enhances the sense of community ownership.
- *Leading to change:* PLA processes involve dialogues about change, which in turn change the perceptions of the participants, particularly their sense and feelings of powerlessness, and motivate them to carry out action, building their capacity to act on their own initiative. This may lead to and/or include processes of organizational change through, for example, local institution building or strengthening.
- *Ethical considerations:* Managing expectations in any participatory process is critical, as well as negotiating, and renegotiating at all stages, the prior informed consent of all participants, ensuring transparency throughout and the sharing of outcomes and benefits.

Methods

The involvement of many people in participatory processes has led to the development or adaptation of innovative and diverse tools and approaches. Methodologies have been developed which use PRA/PLA tools and methods throughout the process. These include the following:

- *Participatory geographic information systems (PGIS)* combine PLA techniques and spatial information technologies to empower and facilitate groups excluded from geographical decision-making processes to carry out participatory mapping.
- *Participatory technology/innovation development (PTD/PID)* aims to move from the conventional transfer of technology to an interactive, multiple-player process of analysis, experimentation and reflection among researchers, local people and facilitators, the product of which could be

innovations that qualify as context-specific technologies. The source of new, credible ideas can also be local innovators.

- *Community-led total sanitation (CLTS)* offers communities the opportunity to understand and analyze their own defecation practices in order to improve local sanitation services.
- *REFLECT (Regenerated Freirean Literacy Through Empowering Community Techniques)* is an approach to learning and social change that started as a fusion of the political philosophy of Freire with the practical methodologies of PRA. It applies these approaches to literacy and empowerment processes as well as gender analysis. REFLECT circles develop their own learning materials based on PLA exercises.
- *Citizens' Juries* and other methods of co-inquiry involve multi-stakeholder dialogues, usually aiming at a process of participatory learning and advocacy.

Challenges

As mentioned above, in order to be effective, PLA tools and methods need to be well facilitated in a non-patronizing way. They are time-intensive, and this has to be factored into planning and budgeting. They also do not necessarily result in the production of the type of quantitative data that is often needed by decision-makers, but rather they can produce qualitative information to complement and back up, and deepen and challenge understanding of conventional findings.

PARTICIPATORY MONITORING

Monitoring of tasks and activities is a crucial aspect of project planning and management, which helps in keeping track of the progress of the project and brings to light the emerging challenges and loopholes. Systematized monitoring at regular intervals not only reflects the status of the project but also hugely informs the future course of action in terms of the changes or modifications required. It creates opportunities for learning, especially from the perspective of Action Learning and research as timely monitoring creates greater opportunities for introspection and self-criticism. Monitoring can be done in numerous ways with different sets of people associated with a particular programme. However, the best way to monitor an ongoing initiative is to involve as many people who are engaged in it at different levels so that it becomes a truly participatory and inclusive process. This method of monitoring activities and tasks where multiple stakeholders, especially the direct beneficiaries, are involved in assessing the development and progress of the project is called participatory monitoring. In recent years, participatory monitoring is increasingly being adopted by civil society organizations, donor agencies and governments to deliver and implement projects and programmes more effectively.

Participatory monitoring, as the name suggests, is a process of monitoring which encourages people's participation in assessing the extent to which an initiative has been successful. It encourages dialogues with the real owners of the process of change, who provide first-hand inputs as insiders, and hence helps in developing a greater sense of ownership and commitment towards the entire process. The other advantage of participatory monitoring is that it blends the best of the indigenous knowledge of the local people (as insiders) with the

acquired and empirical knowledge of those who are facilitating the process (as outsiders), thus bringing to the table a unique combination of shared knowledge and learnings. It also helps in checking that standards are maintained and resources are used in the best possible manner.

For participatory monitoring to function effectively, it is important to understand the following:

- Why monitor
- What to monitor
- How to monitor
- How to incorporate the learnings into future action plans

All of the above-mentioned aspects need to be viewed from the perspective of participatory monitoring and action research, in other words, how far the concerned stakeholders are engaged in monitoring and how far the learnings are being incorporated in the action plans.

Why Monitor

As one of the basic prerequisites of participatory monitoring is the engagement of stakeholders in the monitoring process, it is extremely crucial to have a common understanding of the process of monitoring and why it needs to be conducted. Demystification of the concept of monitoring and its benefits in the long run needs to be done at the onset with the various stakeholder groups, so that when they are involved in monitoring at a later stage they are well aware of the process and also feel committed to it.

What to Monitor

The most important thing to understand before starting the process of monitoring is to define and arrive at a consensus of what is to be monitored. As monitoring is an ongoing activity conducted during the life of the project, the short-term objectives and outputs of a particular phase need to be taken into consideration, and specific activities that are planned towards achieving those outputs need to be monitored in a participatory manner. For example, in a project where one of the objectives is to raise community awareness about different government schemes and the corresponding activity is to conduct community meetings and awareness campaigns, what needs to be monitored is whether the meetings were conducted in a timely manner and what kind of information was disseminated.

How to Monitor

The next step towards monitoring is to do an intensive planning on how to conduct the monitoring exercise.

When talking about the process, the very first step is to develop certain guiding questions based on the objectives and corresponding activities that have been identified for monitoring. Against each question, specific indicators have to be developed to gain relevant information regarding the progress of the same. Once the questions and respective indicators are finalized, a monitoring tool or framework should be prepared. This tool can be in the form of a survey questionnaire, chart or table and so on, which can be easily interpreted by all stakeholders.

For instance, to continue with the above example, the guiding questions that can be generated against the stated activities are whether meetings and campaigns were conducted as stated in the project proposal, whether they proved helpful to the beneficiaries and so on. As far as the indicators for these questions are concerned, they would range from the number of meetings conducted and number of participants in the meetings to the issues discussed and number of participants who started availing themselves of certain schemes. To keep a record of all this information, it needs to be put together in one place in the form of handy formats so that it can be used for future reference.

How to Incorporate the Learnings Into Future Action Plans

Once the results or 'learnings' of monitoring are out, the next step is to collectively reflect on the findings, find out the reasons for the loopholes, identify the limitations and challenges and subsequently alter or modify the course of future actions as per the emerging need. This completes the cycle of action research or learning and provides the project team an opportunity to amend and accordingly replan their actions for the best results.

In all the above-mentioned steps, for participatory monitoring to be delivered in its true sense, it is extremely important to give due consideration and space to the different stakeholders and value the notion of shared decision-making.

PARTICIPATORY RAPID APPRAISAL

Participatory Rapid Appraisal (PRA) is an interactive data collection process conducted at a community level or with a specific community group of interest. PRA is applied at the design, early implementation and evaluation phases of a project cycle or used for environmental and socio-economic research.

Overview

PRA applied to resource management and conservation initiatives puts communities at the centre of the process. PRA recognizes and captures a community's diversity—often with competing interests for the same resource or space. PRA brings stakeholders together to listen to each other to clarify how to tackle the real issues and find a common ground for concerted solutions.

Often, local communities and key persons within the group are the only ones who have information or data on the topic. But this information is scattered and fragmentary; PRA helps to capture and structure local knowledge.

After defining the PRA objectives, the facilitator undertakes a stakeholder analysis to identify who has information and the vested interests. The wider the representation, the stronger will be the ownership by the community and the easier the implementation of actions identified during the PRA.

The PRA Process

PRA's are intensive rather than extensive and are generally conducted in various groups for logistic and socio-dynamic reasons. Organizing the information gathering in different sessions contributes to cross-validation of the information (referred to as triangulation).

The group or organization conducting the PRA works with a facilitator, with whom the objectives of the PRA and a core question are defined. The core question is discussed with the participants and is clearly visible during the process. Examples of core questions are as follows:

- How can sustainable use of shrimp fisheries in the river estuary be planned?
- How can shark overfishing in West Africa be addressed?

PRA field sessions bring the different stakeholders together in a neutral venue to address the core question. PRA targets illiterate groups; hence, facilitators generally use qualitative tools as explained below. The facilitators proceed with the participants in two phases:

(1) drafting of their knowledge and then (2) reorganizing the information interactively.

Plenary sessions consolidate the information obtained from the different focus group meetings and have four functions: (1) explaining, (2) reporting, (3) exchanging and (4) common decision-making. During plenary sessions, a facilitator explains the process objectives and methods, focus groups report their outcomes and participants exchange, debate and reorganize or prioritize issues and make common decisions.

Focus Groups

Focus group sessions aim to facilitate participants' expression and diversity. They take no more than 1 hour and consist of no more than 15 people.

Focus groups should have a facilitator chosen among themselves to maintain focus, keep the discussion flowing and balanced and record the group outputs. For each idea, a short sentence of eight words, grading tables or graphs should be presented. To facilitate interaction among participants, it is advisable to diversify the focus groups in various ways:

- Grouping by homogeneous community members in the early sessions, such as men in one group and women in another or fishers with gill nets versus surrounding nets
- Mixed grouping for common topic analysis
- Voluntary grouping for in-depth analyses and planning of recognized relevant issues
- Specialist groups (as necessary)

Prioritization

PRA is a transparent and progressive prioritization process from group work to the plenary session. In most cases, after an exchange of views, a voting system is organized to strengthen the sense of communal-ity and linkage among the stakeholders.

Tools

PRA frequently targets non-formally educated people and is meant to gather the maximum information in a minimum amount of time. The information is sourced from ancillary data, semi-structured interviews or focus groups. Focus groups are the most frequently used tool. Descriptive statistics and qualitative information-gathering methods that utilize matrices, tables, signs, maps and figures are also used.

Tables and matrices are usually used in all phases and for different groups. Tables usually capture one idea, while matrices collect many aspects of a process. Scaling and descriptive words or signs are filled in tables and matrices. Graphs and drawings such as

a seasonal calendar, maps, diagrams and transects are another set of tools used. The seasonal calendar captures the annual seasonality of an activity or event and is used to capture changes over time by comparing different dates. Maps capture the spatial distribution of features. These two tools are usually filled by specialists and a restricted group. Diagrams and transects can be utilized by all types of people.

Synthesis

The synthesis phase conducted by the organization conducting the PRA often combines PRA information with a review of secondary documents collected during and after the PRA exercises to produce a draft report. The synthesis report usually contains climate, demographic, economic and ecological data.

Content of the Report

The draft report includes background, description, analysis and recommendations. The descriptive component of the report is a synthesis of the questions and answers from different sessions. The analysis component integrates responses and identifies relational causes and hidden trends for better decision-making. Stakeholders' priorities must be included clearly in the draft.

Validation

A draft report should be circulated and, in a meeting, presented to stakeholders for review and validation. While PRA sessions are open to the community at large, validation meetings target key stakeholders.

A validation meeting can be conducted in three phases: (1) amendment and validation, (2) prioritization and planning and (3) expectation and commitment.

The survey time is not adequate to fully address the planning stage, though the validation meeting will have a planning session where priorities are revisited and objectives are defined.

Implementation

A PRA session shall have a follow-up programme to make the process reliable; it is a form of action research conducted to solve a local issue. The process raises the stakes and often finds clear solutions that are planned to be progressively implemented, or constraints are discussed at the validation session.

Conclusion

PRA is a bottom-up and inclusive problem-solving, project planning and implementation, community mobilization and research process. The process is

designed and led by local people. It is an intensive approach to community engagement.

PARTICIPATORY RURAL APPRAISAL

Participatory Rural Appraisal (PRA) is a methodology used for interactive processes of social development: It is a way of learning from people, with the people and by the people. It is, therefore, a methodology for analyses, planning, monitoring and evaluation. Subsequently, PRA came to be known as Participatory Learning and Action (PLA), a name promoted during the latter half of the 1990s by the journal *Participatory Learning and Action (PLA)*. Originally called *RRA* (Rapid Rural Appraisal) *Notes*, then *PLA Notes*, this journal is published by the International Institute for Environment and Development (see www.iied.org/pla).

PRA or PLA combines the strengths of the constructivist paradigm and critical realism. From the former, PRA/PLA seeks to understand in an interdisciplinary framework human experience as it is lived and felt; from the latter, PRA/PLA seeks help to evaluate such analysis and correct errors and biases through multiple sources, methods, locations and other means.

Origins and Evolution

The origin of PRA/PLA and other such approaches can be traced back to a multitude of approaches which gradually emerged since the 1970s mainly due to the sub-optimal results from the applications of conventional methodology of understanding rural development. The conventional questionnaire survey and its final outputs are time-consuming, long and tedious, involving people (respondents) playing only a passive role

in answering the structured questionnaire designed by specialists based on their own world view, where analysis by the people themselves did not occupy a central place. The disillusionment with the conventional questionnaire surveys and their outputs surfaced, and alternatives to the questionnaire survey were explored. A host of other field methods were also evolving during this time that were relatively more efficient in yielding the same quantity of information, or even more, in a short period of time vis-à-vis the survey method. Such methods from various sources were put together as RRA. RRA can be described as a way of organizing people for collecting and analyzing information within a short span of time, involving direct interaction with the people in a limited manner to draw inferences, conclusions, hypotheses and assessments, which includes acquisition of new information within a limited period of time. A host of other methods which appeared during the time include Sondeo, agroecosystem analysis, diagnosis and design, and exploratory survey.

As a methodology, however, RRA remained 'extractive' in that the outsiders (e.g. the researchers) observed, analyzed and wrote, though it was a great approach in terms of making people's participation an integral part of it. Thus, one of the essential elements of the new paradigm of development, that local people make their own analysis, was still missing, and the need for a quicker method of collecting data and also making the process less extractive emerged. In essence, the need was to have a tacit shift from 'extractive' to 'participatory', from 'narrow-based' to 'broad-based' approaches in terms of more participation and a greater range of applications. It was a shift of emphasis from 'rapid' to 'participatory' that was called for, which was in consonance with the paradigm of participatory development. That became the starting point of PRA, the development of an interactive process of social development extensively used throughout the world.

Principles of PRA

The guiding principles of PRA are as follows:

1. PRA is based on the principle of listening to, and learning from, people through participatory interactions and learning rapidly and progressively.
2. PRA learns from, rather than lectures to, people.
3. PRA should be free of biases (e.g. professional, roadside, time, seasonal, gender, people and beneficiary bias).
4. PRA optimizes trade-offs: relating the costs of learning to the useful truth of information, with trade-offs between the quantity, relevance, accuracy and timeliness of information.

5. PRA adopts the principle of optimal ignorance: not knowing what is not worth knowing and knowing things with appropriate imprecision, not measuring more than what is needed.
6. PRA follows the principle of cross-checking and triangulation: cross-checking the reliability and validity of information by putting it to different tests, changing the methods for collecting information, changing the locations, timings, groups of participants and teams conducting PRA and so on.
7. PRA seeks diversity: deliberately looking for, noticing and investigating contradictions, anomalies and differences.
8. PRA encourages the principle of 'people doing it', or 'they do it'. The people themselves facilitate, investigate, analyze, present findings and learn. This has also been called 'handing over the stick' or 'handing over the pen'.
9. PRA embraces error and self-criticality and responsibility, meaning that those who facilitate the PRA process are continuously examining their behaviour and trying to improve, recognizing errors if any as an opportunity to learn to improve.
10. PRA shares information: between people, between the people and outsiders (facilitators), between different facilitators and between organizations.

Clearly, the principles are both operational, such as cross-checking and triangulation, and behavioural, such as embracing error, seeking diversity and 'handing over the stick'.

Methods of PRA

As noted earlier, PRA is a methodology used for interactive processes of social development and for analyses, planning, monitoring and evaluation. This methodology, like any other methodology, has various tools. Some of the key tools are secondary data review, direct observation, observation indicator checklists, semi-structured interviews and sequences or chains of interviews, focus group discussion, preference ranking and scoring, pairwise ranking and scoring, direct matrix ranking, ranking by voting, wealth ranking and well-being ranking, innovation assessment, diagramming, mapping and modelling, participatory mapping, historical and future vision mapping, mobility diagramming, social network mapping, transect walk, historical transect, seasonal calendar, timelines and trend analysis, historical profiles, livelihood analysis, Venn/institutional diagrams, systems diagram, causal

diagram, force field analysis, empowerment circle, pie charts, histograms, health analysis, oral histories, group walks, storytelling, case studies and portraits, taxonomy and ethno-classification and participatory analysis of aerial photographs.

Pillars of PRA

From the principles and methods one can infer that PRA has four pillars: (1) attitudes, (2) beliefs and behaviour, (3) process and (4) methods and sharing. Application of PRA methods is not a random exercise. There is a process involved in applying the methods. Further, a researcher cannot properly apply the methods unless she or he believes in the wisdom of the people and is willing to learn for them, 'hand over the stick' and listen and learn. Finally, the outcome of PRA exercises must be shared (the 10th principle); it should not be merely extracting information and data.

Uses of PRA

PRA has been used extensively in many parts of the world. PRA approaches and methods have been used for appraisal, analysis and research as well as planning and evaluation in many subject areas, which include agroecosystems; natural resources, forestry, fisheries and environment; irrigation; technology and innovation; food security; health and nutrition; farming systems research and extension; pastoralism; marketing; disaster relief; organizational assessment and design; social cultural and economic conditions and many special topics such as general elections and evaluation of poverty reduction strategies of countries seeking World Bank assistance.

PARTICIPATORY THEATRE

This entry defines Participatory Theatre (PT), situating it amongst other practices belonging to the larger term *Applied Theatre*. Five different forms of PT are highlighted and described, with the intent to give the reader an idea of how they can be used in action research. Connections are made between action research as a methodology and PT as a practice, and how one can augment the other.

PT is a term given to theatre practice that generally plays an educational or interventionist role, that involves its audience in discussion and dialogue about the performed piece and in which the audience and the performers or presenters interact during and/or after the performance. Applied Theatre is the umbrella term for the great variety of theatre practices that are participatory and is an inclusive term to describe theatre presentations that fall outside the bounds of mainstream theatre performances. Applied Theatre is the practice of theatre that has been adapted, shaped, morphed and re-deployed by practitioners, educators and facilitators to bring about, for both participants and audiences, a heightened awareness of human and social issues through a focus on a particular topic. The goals of this form of theatre challenge societal norms and encourage reflection in order to bring greater understanding with a view to empowerment of its participants. Some important characteristics of Applied Theatre are that it can be practised outside of conventional theatre spaces, in classrooms, community halls, work spaces or village settings, or out on the streets; that the project may involve a performance or it may not; that it may include trained actors but often does not and that the spoken text generally emerges as a result of an improvisatory process rather than reliance on a script pre-written by a playwright.

Since the 1960s, more and more theorists of Applied Theatre have defined and made distinctions between its various practices. Now there are over 30 different titles for practices that fall under the umbrella term *Applied Theatre*. Theatre in education (TIE), drama in education, theatre for health education (THE), museum theatre, reminiscence theatre, popular theatre, community-based theatre, prison theatre, playback theatre, Theatre of the Oppressed and theatre for development (TfD) may be identified as the more prevalent and can be found in many parts of the world. At the heart of any of these practices is the element of participation, which

brings together through collective creation individuals concerned or passionate about a particular topic.

The following five types of theatre are strongly associated with Participatory Theatre: (1) forum theatre, (2) playback theatre, (3) TIE, (4) popular theatre and (5) TfD.

Forum Theatre

Forum theatre was first developed by the Brazilian theatre director Augusto Boal, originating out of his research on creating a theatre form that is liberating and empowering for marginalized and disadvantaged people. This practice he called 'Theatre of the Oppressed'. Forum theatre consists of performing a play or a series of scenes and is created with the purpose of highlighting a situation where an individual or a group is oppressed by another individual or group. The performance is taken to the community whose issue is being investigated and played in its entirety once. The performance is then replayed, and the audience is invited to stop the performance at moments when they see an act of oppression taking place. The audience member who stopped the performance is then asked to make suggestions to the actor playing the character of the oppressed individual as a means for that character to resist the oppression. Sometimes, the 'spect-actor' will perform his or her own suggestions within the scene. It is quite common for suggestions that are then played out to meet with obstacles or negative repercussions as the other characters respond to this new input as they think might happen in real life. Someone from the theatre group, called the 'Joker', is assigned the task of 'liaising' between the audience and the performers. The role of the Joker is very important in keeping the dialogue alive and current and within the bounds of what the drama is exploring. At times, the audience feels the need to change the actions of the oppressor, but that goes against the rules of forum theatre, which focuses on creating change instigated by those who are oppressed, because it is they who need to find their voice. Forum theatre is widely used internationally in developed and developing countries, where oppression is in some cases overt and in others, less obvious. As a result, it is a form of theatre that demands careful attention to subtleties and nuances in the performance. Although extremely challenging for everyone involved, when forum theatre is carried out in the way for which it was initially designed, the results can initiate a process of social change.

Playback Theatre

Playback theatre originated in improvisational theatre and was developed by Jonathan Fox and Jo Salas

in 1975 in New York State. The practice consists of a company of performers trained extensively in the methods of improvisational theatre replaying stories and experiences that usually revolve around a particular theme or topic. A facilitator, part of the playback company, invites audience members to tell their story, all the while listening intently and only asking questions that illuminate a particular part of the story that is otherwise unclear. The performers then proceed to replay the story that the teller told, infusing it with dramatic movements, gestures and sounds that bring the events to life. The result is often moving for the person telling the story, and also for those listening as it brings to life similar experiences they may have had or experiences they may not have known about. Playback offers an example of the scaffolded learning that community participants offer to each other when they are able to share their stories, and it has a history of therapeutic use.

Theatre in Education

TIE originated in England in the 1950s, when local theatre companies went to schools and worked with teachers to create plays about topics explored in the curriculum. The performances were staged in the classroom, in the gymnasium or in the study hall of a school and so broke the convention of staging a performance in a conventional theatre space. Initially, the British government generously supported this kind of community outreach, and theatre companies thrived, solidifying and codifying the practice so that it became known and practised in other parts of the world (e.g. Australia, North America and other parts of Europe). In the 1980s, government funding cuts meant that a number of companies could no longer continue to practice. Other companies, although no longer able to collaborate with teachers, continued to work with topics that they felt would be pertinent to the educational curriculum, and today bullying, discrimination against gays and lesbians and the alienation of immigrant and refugee youth from the mainstream school system are current issues that engage TIE companies and their audiences. The audiences are often asked to participate in the performance in various ways (e.g. through the taking on of roles, making decisions, giving advice, etc.), and the performance is always followed by some sort of discussion around the topics explored; the purpose is to create a space for sharing, reflection, possibly action and, hopefully, awareness and ultimately changes in understanding.

Popular Theatre and TfD

Popular theatre and TfD are practices that are similar in context in that they are both aimed at empowering

marginalized or disenfranchised communities by facilitating ways for social change through theatre; both practices are 'community based', which means that the drama is created by the actual community members and not by trained performers, who are generally outsiders to the community (as in forum theatre, TIE and playback theatre). The difference between popular theatre and TfD is that the former is solely conceived and realized by the community, with no external influence on the group's agenda or execution of the practice, whilst the latter is typically funded by an outside agency (not-for-profit organization) that controls the agenda and the focus of the topics to be explored in the workshops and performances (if part of the process). There is not an agreed-upon origin for the practice of popular theatre, except that it began to emerge in Europe in the 1920s and 1930s and in North America the 1970s and 1980s as when people sought to use creative ways to challenge the status quo and to involve communities in questioning political and social norms. Driven by the need to reclaim the dignity and rights of people, theatre facilitated the creative environment in which to unite people in achieving a common goal through an invigorating and uplifting practice.

TfD originated in post-colonial Africa in the 1960s as a means to disseminate messages from governments and organizations to communities to create social awareness. Over the years, practitioners of TfD noticed that communities felt misrepresented in the performances and, hence, the messages had little impact on their actions. In the 1970s, TfD practitioners began to involve communities in the dramas by having them participate in conceiving the issues to be represented in them. This method, although it brought the content closer to the community's issues, still needed improvement. By involving communities in creating and performing the dramas, in the 1990s, Michael Etherton created groundbreaking TfD where young children in Bangladesh expressed what they knew to be their rights and not just their needs. It is of particular importance to mention that the evolution of TfD mirrors elements at the core of action research, such as (a) using research to solve real problems, (b) understanding social challenges through the eyes of community members, (c) collaboration between research team and community members, (d) inclusiveness of participants, (e) research agenda and goals driven by participants.

Using Participatory Theatre in Action Research and Vice Versa

The above-described theatre practices are strong choices for individuals interested in doing research firmly based in participants' lived experiences. For each type of theatre practice, there are dynamics

of power and ethics that must be considered and acknowledged in the research plan. The dynamics of power can become complex when the research team is collaborating with theatre facilitators to conduct the participatory project, as there will be a number of agendas to navigate and negotiate. It is common for Applied Theatre practitioners pursuing academic research through their practice to struggle initially because they find the existing qualitative research methods to be rigid and heavily based on data collection and analysis. What is useful for these practitioners to know is that inherent in any Applied Theatre participatory practice are the fundamental constructs of action research, particularly in the way it is carried out through the spiral nature of the methodology in three stages: (1) careful planning of the action or intervention (planning of workshop sessions or rehearsals); (2) implementation of the plan (intervention), all the while carefully documenting the results (carrying out the workshop, rehearsals or performance), and (3) re-planning by adjusting interventions based on the findings from the first stage (planning for a second workshop, rehearsal or performance) of the spiral. The three stages follow each other recursively whether conducting short-term theatre workshops or long-term projects that span over several years. Working in this manner enables theatre practitioners not only to document their work but also to base their evaluations and plans on the evidence collected in workshops/rehearsals. Also, it is a clear means of keeping track of the challenges, successes and advancement of (and, at times, changes to or alteration of) their project goals. Such evidence-based practice can be extremely helpful documentation when applying to funding bodies or finalizing the funding report at the conclusion of the project.

PARTICIPATORY URBAN PLANNING

Traditional urban planning methods have witnessed a top-down approach, with limited or no grass-roots-level involvement. For developing countries, where cities tend to expand in an organic manner, the traditional approach has proved to be rigid, and its result has been adverse, reflecting little understanding of local-level issues. Community involvement is an effective tool that ensures the sustainability of an urban development project by addressing the needs of stakeholders in a diverse beneficiary set. By definition, participatory urban planning is an urban planning paradigm that emphasizes the involvement of the entire community in the strategic and management process of urban planning, thereby giving rise to community-level processes. It thus shares the Participatory Action Research elements of recognizing the importance of marginalized citizens' active participation in knowledge creation and subsequent collective actions, leading to their empowerment.

Purpose

Participatory urban planning is a planning approach that bases planning solutions on the requirements of the end user, as opposed to a blind top-down approach by planning experts to base planning solutions purely on statistical data. In addition to bringing forth local issues and the felt needs of a community that require attention, participatory urban planning works as an empowerment tool. It brings forth consensus where there is a multiplicity of interests, gives voice to marginalized groups within a community, allows for the inclusion of local knowledge and know-how into established design methods and brings about accountability in local governance.

Difference From Conventional Urban Planning Approaches

Conventional urban planning approaches are dominating, treating the community as ‘beneficiaries’ of solutions provided by planning experts, and the resolution for planning problems is carried out through a normative project methodology. It projects reliance on statistical data and, owing to its top-down approach, entails minor, local-level involvement. In contrast, participatory urban planning allows local knowledge to form the basis of planning solutions. The direct involvement of the community takes place at all stages of planning, allowing them to become contributors and decision-makers instead of being treated like an audience that is provided information once decisions have been made. Additionally, participatory planning provides inclusion of the diverse interests and focus areas (often a result of social constructs) within a community.

Achieving Community Participation

The process of incorporating community-level involvement consists of a series of actions that ensure that community members are providing input at every stage of the planning process. As a result, the community’s involvement begins at a microlevel with their participation at the neighbourhood level and goes up to the macrolevel with their participation at city-level meetings.

At the onset of a project, an exhaustive reconnaissance survey of the area of interest needs to be carried out so that existing resources can be noted. When juxtaposed against the voiced needs of the community, the results of this survey help create a realistic image of the requirements of the project. Subsequently, the stakeholders are encouraged to voice their needs and concerns. At the onset, there may exist an apathy to the planning process within the community owing to unpleasant past experiences in urban development projects where the community’s needs may have been overlooked or the community may have been coerced into accepting the planning solutions provided to them. The presence of community-based organizations and an increased level of awareness relating to participation create a more enabling environment for the community to participate. It is important at this stage to note and encourage the involvement of the marginalized groups in the community (e.g. women, senior citizens, youth and minority groups) in order to create a holistic set of requirements for the project. This step is especially challenging as it requires overlooking the social hierarchies existing in the community based on age, gender and economic status and urging representation from all groups within the community.

In the next step, a database needs to be created that contains the basic information regarding the community, including (but not limited to) the physical characteristics of the settlement, socio-economic characteristics of the community, condition of services and amenities provided in the area and so on. The involvement of the community at this stage ensures that an authentic and complete data set is created. Simultaneously, a continuous dialogue needs to be maintained with local officials and the departments concerned with the planning process. Building of partnerships at this stage ensures that there is co-operation from the power holders at the time of decision-making and that there exists empathy for the community at the governance level.

In the next stage, ward-level stakeholder consultations are carried out, which should involve representation from the community as well as important groups pertaining to the community—market organizations, informal-sector representatives, religious groups as well as members of the local government. Through focus group discussions and small workshops, exchanges with the community can take place to augment the process of identification of issues.

Subsequently, a city-level meeting is organized where all the collected data is placed before representatives of the community and strategies for development are discussed. These inputs then lead to the preparation of the draft plan for the project. This is again placed before the community in workshops and meetings conducted at various points during the revision of the plan. The inputs garnered are then translated to create the final plan, which is then presented to higher authorities for approval.

Achieving Community Empowerment

Specific steps taken during the planning process can ensure that the community feels more connected to the project in terms of data collected and decisions taken. This can be done through the creation of data ownership by involving the community in the collection of data for the physical limits of the settlement (e.g. slum profiling using global positioning systems) and socio-economic data (settlement profiles and primary household surveys). This process not only uses the local knowledge available within the community but also helps create an authentic database.

To summarize, an inclusive planning process is one that treats members of the community as more than just passive data providers and ensures their involvement at all decision-making levels while valuing multiplicity of interests.

PERFORMED ETHNOGRAPHY

Performed ethnography involves turning ethnographic research findings into play scripts that are read aloud by a group of participants or performed for audiences. The richness of performed ethnography comes from three sources: (1) the ethnographic research from which a play script is created, (2) the reading or performance of the play and (3) the conversations that take place after the reading or performance. In these follow-up conversations, research participants and other readers or audience members have input about the conclusions of the research. This allows for ongoing analysis of the research findings. The incorporation of audience input into ongoing revisions of the play provides an opportunity for mutual analysis and, in so doing, can help create more ethical and participatory relationships between researchers, their research participants and the communities to which the research participants belong. Post-reading/performance conversations about a play also allow researchers to share their findings in classrooms and other public forums. Performed ethnography, then, offers action research a compelling way for research participants to comment on the researchers’ understandings and analysis. It also offers action researchers a way to engage a wide variety of audiences in the discussion of their findings.

Defining Performed Ethnography

Performed ethnography is also known as performance ethnography and ethnodrama. Norman Denzin uses the term *performance ethnography* to refer to performances that ethnographers stage from their interviews

and observation field notes. Johnny Saldaña describes an ethnodrama as a dramatic script that consists of significant selections of narrative that have been collected through interviews, observation field notes, journal entries, diaries, media articles and court proceedings. For Saldaña, ethnodrama is different from ethnotheatre, which uses the traditional craft and artistic techniques of theatre production to mount a live performance event of research participants’ experiences and/or a researcher’s interpretation of data. In ethnotheatre, the fieldwork conducted by a researcher is preparation for a theatrical production.

Like Saldaña, Jim Mienczakowski and Teresa Moore believe that ethnodrama is different from traditional theatrical work. They describe it as a new aesthetic that values the accurate interpretation of research findings over the style, mode and traditions of theatrical presentation. For Mienczakowski, the audiences for ethnodrama work are often composed of those with a close relationship to or lived experience of the themes of the piece, and their anticipation of performance and entertainment are secondary to their expectations of theatrical engagement. The performance is a shared context that actors and audience members co-construct and relate to because of their own emotional links to the topic of the research and/or performance.

Dramatizing Research Findings: Monologue and Dialogue

Performed ethnographers dramatize research findings in a variety of ways. A monologue is an extended, one-person dramatic narrative that provides a portrait of a character based on an actual research participant or set of research participants. Autoethnographic monologues are narratives that are generated by the researchers themselves. Saldaña explains that monologues are composed of particular dramatic elements and structural forms. Knowledge of these enables a researcher to craft a more aesthetically shaped work for the stage. Dialogue consists of two or more characters who engage in verbal action, reaction and interaction and is embedded in a dramatic story. As not every ethnographic study provides the necessary detail for the replication of authentic or verbatim dialogue, performed ethnographers sometimes imaginatively reconstruct dialogue that represents the cultural moments, conflicts and events documented in their studies. Such writing is often called creative non-fiction or ‘faction’ (a blended word from fact and fiction) and raises questions about representation and truth in performed ethnography. Action researchers working with the approach of performed ethnography need to work with research epistemologies and ontologies (theories

of knowledge and reality) that are compatible with the creation of creative non-fiction.

The Multiple Commitments of Performed Ethnography

As a hybrid writing method that links ethnographic analysis to dramatic writing, theatrical performance and critical discussion, performed ethnography demands multiple commitments from the researcher. These commitments sometimes compete and lie in tension with each other and present the researcher with a set of dilemmas. For example, performed ethnographers may find themselves privileging particular dramatic and storytelling techniques over the words and ideas put forth by their participants. The imperative to begin a play with an exciting dramatic moment and to introduce the main character to the audience raises the question of which stories and findings from a research study get told and which do not. Performed ethnographers need to articulate the ways in which they have identified the multiple commitments underlying their work and the ways in which they have responded when one or more of these commitments have come into competition with another. This requires self-conscious reflection on the various roles performed ethnographers play: ethnographer, playwright, educator and activist. Important aspects of a researcher's reflection can be made available to the readers and audience of a performed ethnography through the convention of 'playwright's notes'. Playwright's notes, which often appear in programmes of theatre performances, are a place for playwrights to discuss aspects of their plays that they think are important for the audience to know about. For example, some playwrights discuss the historical period and/or geographic location of their plays; others discuss the prominent themes that are embedded in the play or the actions of a particular character. Playwright notes are often reflections on aspects of a play that may not be immediately evident or visible to the audience. Similarly, 'performed ethnographer's notes' can contain reflections on the tensions and dilemmas of writing and performing an ethnographic play script that may not be immediately visible to the reader, performer or audience.

The reading or performance of a performed ethnography provides an opportunity for researcher-participants, readers and audiences to come together to hear and discuss important stories about the human condition. It has much to offer to action researchers who are interested in socially engaged and participatory research practices.

PHENOMENOLOGY

In its broadest sense, phenomenology is a philosophical movement which arose as a reaction against the predominance of an approach to science epitomized by objectivity, abstraction and rationality. Phenomenology's recognized founder, the German philosopher Edmund Husserl (1859–1938), argued for a return to 'the things themselves' rather than abstract ideas of them as a valid and important means of achieving knowledge. Husserl recognized that a central aspect of 'the things' is their significance to human beings and our lived experience of them. Through reclaiming day-to-day, subjective experience as a means through which knowing is created, phenomenology repositions the knower in his or her own world as central to that which is known. This stance indicates an important link between phenomenology and action research: As an approach to undertaking research located within as well as valuing the day-to-day contexts of the researcher and the researched, action research is clearly aligned with phenomenology's philosophical intentions. This entry provides a brief historical account of how this approach emerged, before it identifies and elaborates on four of its key concepts: (1) the lifeworld, (2) intentionality, (3) the difference between ready-at-hand and present-to-hand knowing and (4) the phenomenological method. Explicit links between phenomenology and action research are then offered.

Historic Groundings

In order to understand phenomenology, it is critical to consider the landscape of ideas from which it arose. Since the time of René Descartes (1596–1650), science had been developing in a way characterized by an increasing disregard for lived experience and the body

as a source of ‘truthful knowing’. Rather than relying on faulty bodily senses, ‘truth’ was seen to be achievable through abstractions and the application of formal rules of logic. Rather than relying on experience, ‘ideals’ were the touchstones for determining knowledge.

The importance of subjective experience was not totally lost, however, and the term *phenomenology* was used by philosophers as early as the eighteenth century to signify the role played by human experience as a source of knowing. The two German philosophers credited with introducing the term in the way taken up by Husserl, however, are Franz Brentano and Ernst Mach. Most famously, Mach suggested that electricity should be described in a way that embraces our ‘experiences’ of it. This indicates the importance phenomenology places on ‘human experience’ rather than just the physical properties of a phenomenon. In his *Introduction to Phenomenology* (2000), Dermot Moran suggests that in this way phenomenology recaptures the richness of human experience and makes it a valid field for knowing.

Husserl outlined his phenomenological project in two volumes, *Logical Investigations 1 and 2*, published in 1901 and 1902, respectively. However, a lecture presented rather late in his life in Vienna in 1935, titled *Crisis of the European Sciences*, sets out the need for a phenomenological approach most clearly. In it, he argues that the kinds of questions which positivist science is equipped to answer are not those of crucial import for human beings in the living of their lives. For instance, natural science cannot begin to answer questions such as ‘What is it to live a good life?’, ‘How should I demonstrate my care for other human beings?’ or even ‘Who am I?’. In other words, although positivist science can be helpfully applied to understanding the world ‘as it is’ from a physical standpoint, it cannot answer questions such as ‘How should the world be?’ or, more important, ‘How do I experience the world?’. Such vital questions require an approach which affords human experience a central role.

Husserl’s ideas were developed by a number of other philosophers, most notably by his student Martin Heidegger, whose work transformed many of the ideas Husserl first introduced. Others focused on particular aspects of the approach; for instance, Hans Georg Gadamer developed phenomenological hermeneutics, and Maurice Merleau-Ponty elaborated the phenomenology of perception. It must be noted that there was a great deal of discord amongst those who took up the phenomenological banner, so much so that in his *Briefwechsel IX* of 1931, Husserl declared himself the ‘greatest enemy of the so-called phenomenological movement’. This points to a challenge for researchers trying to define phenomenology precisely—those most closely associated with the movement cannot

themselves agree on its exact terms. However, some general characteristics which would be agreed on by most of those who align themselves with this movement include the following:

- It began as a reaction against the predominance of a science dedicated to abstraction, ideals and objectivity and reasserted the importance of human experience in knowing.
- It attends to the day-to-day world of experience (the ‘lifeworld’, which will be explained in greater detail below) as a source and means of knowing.
- Research methods aligned with it (including one known as ‘the phenomenological method’) delve deeply into the ‘felt experience’ of a phenomenon or situation. Deep dive subjectivity, rather than the possibility of objectivity, is what these methods seek to achieve.

Key Ideas

Although, as has been indicated above, there is not one precise definition of phenomenology, there are a number of concepts which are generally recognized as central to its understanding. Four of the most important ones, the lifeworld, intentionality, the distinction between present-to-hand and ready-at-hand knowing and the phenomenological method, are elaborated in the following sections.

The Lifeworld

The ‘lifeworld’, or *Lebenswelt* as Husserl called it, is the ordinary world in which we live and act. Although this may seem unimportant to identify as a sphere of action or being, it has to be seen in relation to the ‘scientific’ view about how truth is developed—within the laboratory or through abstract thought experiments rather than within the breathing, living world that we inhabit on a day-to-day basis. Phenomenology reclaimed the ordinary, quotidian aspects of living as a valid context within which knowledge can be developed.

In its recognition of the lifeworld as an important venue for learning and knowing, phenomenology can be seen to be especially linked to action research. Through a phenomenological perspective, the environments in which we actually live and work and play are seen as valid locations for conducting research. The phenomenologists purported that there is distinct and important knowing that comes through engagement with the lifeworld, especially in relation to practical knowing. After all, knowing the laws of physics which hold a table together may have importance to a

physicist, but they are of little consequence to a family gathered together around one to celebrate births or grieve after deaths. Although the meanings attributed to such a table and its significance in social discourse cannot be ‘measured’ by laboratory instruments, its role as a signifier in our social worlds is no less important in our day-to-day engagement with it. In failing to understand and give value to the social role things, concepts and other humans play in our lives from this meaning point of view, we miss out on an essential form of knowing. Action research draws from this commitment to the lifeworld as an appropriate sphere of study through its insistence on attending to the practical issues of the communities within which we are located.

Intentionality

The notion of ‘intentionality’ is central to phenomenological understanding and similarly has important implications for action research. Most significantly, it has a very different meaning in phenomenology from its meaning in more common usage. From a phenomenological perspective, intentionality refers to an essential aspect of consciousness; that consciousness is always a consciousness *of*. Rather than being a quality of ‘action’ then, intentionality becomes a quality of consciousness within the phenomenological context.

In proposing this stance, phenomenology blows open the ‘black box’ of consciousnesses associated with Cartesian views of the world. From a Cartesian perspective, consciousness happens within human beings in isolation from the external world. Our consciousness operates separately from the things of the world and alights on them as it chooses to. However, the term *intentionality* implies that without the things of the world to be conscious of, there would be no consciousness. In this way, phenomenology offers an ecological system of consciousness, one which is in constant and dynamic association with the world beyond it.

The notion of intentionality reinforces the validity of attending to those things in our everyday experience which snag our attention as important topics of research interest. Instead of basing inquiries on abstract conceptual problems, both action research and phenomenology encourage us to attend to what we are conscious *of*, in the outer world as an originating site for research.

Ready-at-Hand and Present-to-Hand Knowing

This is a distinction elaborated by Heidegger in his text *Being and Time*, which was originally published in 1927. Heidegger suggests that there are two prime modes of relation to the things of the world. ‘Ready-at-hand’ constitutes the everyday, almost unconscious

way in which we engage with the world. In an oft-cited example, he describes the experience of working with a hammer. When you pick up a hammer to nail a tack into the wall, you don’t think about the hammer itself, but you think primarily of the job it helps you accomplish. It is an instrument by which you can achieve the goal of hanging a picture on the wall. In such an instance, it is natural to engage with the hammer without really thinking of it, its dimensions, the materials it is made of or, in fact, many of the things that natural science would find as key ways of describing the hammer. Your primary interest is in accomplishing the job the hammer enables you to do. In this way, you are engaging with the hammer in a ready-at-hand mode.

However, should the hammer break—its head falls off or perhaps its handle splits—and you are not able to pound the nail into the wall, you might stand back and engage with the hammer in a different way. You would look at it carefully to try to determine what has gone wrong with it. You would notice, perhaps, that the fitting for the hammer head has become a bit loose or that there is a small crack in the hammer’s head itself which prevents it from working with the required force. In this process of stepping back and assessing the hammer in this way, you are engaging with it in a ‘present-to-hand’ mode. The hammer is no longer doing what it is meant to be doing. Instead, you are regarding it from an abstract point of view, in a way that is very different from your ready-at-hand interaction with it.

Phenomenology brings our attention to the fact that things are known differently depending on whether we are engaging with them in a ‘present-to-hand’ or ‘ready-at-hand’ manner. Things are perhaps ‘more themselves’ when they are in the ‘ready-at-hand’ mode—when we are working with them without thinking about them, when they are just ‘doing their job’. However, the minute we want to study them and distance ourselves from them, they become curiously ‘different’—they take on an altered mode of being in the world. In a way, they have momentarily stepped out of our lifeworld. It is not to say that one is right and the other is wrong, but each form of engagement yields different ways of knowing the thing in question.

This distinction is helpful to action researchers because in its quest to improve practical situations, action research often attempts to work in a ready-at-hand rather than a present-to-hand mode. Through methods such as Participatory Action Research, action researchers engage with issues of real consequence as they unfold, with the people for whom that unfolding is most significant rather than in simulations or experiments. They turn their focus on here-and-now engagements in methods such as Co-Operative Inquiry, and they experiment with the impact of new behaviours through cycles of action and reflection in Action

Learning sets. Although it could be argued that any time researchers step back to reflect on a phenomenon or interaction they are moving from the ready-at-hand to the present-to-hand mode, there is a difference of degree, and in its choice of research contexts and the means of examining them, action research leans towards the ready-at-hand mode of operating.

The Phenomenological Method

Husserl initially offered the possibility of a 'phenomenological method'—a 'reduction' which would enable the inquirer to engage with the 'essence' of things themselves. Although subsequent phenomenologists disagreed with the specifics of how this reduction could be achieved, its basic idea, that it is helpful to peel away our own preconceptions of 'things' in order to encounter them, was a starting point for its development. This phenomenological method was perhaps best elaborated in the work of Goethe, particularly through his attention to colour analysis. The nub of the method is to engage with a thing in such a way that all of your own preconceptions of what the thing is peel away. The goal is to 'bracket', that is, set aside, everything that you know about the thing in order to encounter its very essence. Of course, it is impossible to do this completely. However, concentrating on a particular thing in this way fosters a particular kind of attention through which the quality of consciousness itself shifts, and one is more readily able to distinguish one's conceptions of the thing from the 'thing' itself.

Whereas phenomenology refers to bracketing as a way of accomplishing this, action research encourages a parallel practice of 'critical subjectivity'. When exercising critical subjectivity, the researcher strives to bring to more conscious awareness the assumptions and perspectives which colour situations in order to better comprehend the role their subjectivity plays in creating and interpreting them. In using both the phenomenological method and critical subjectivity, the goal is not necessarily to arrive at a place in which there is no subjectivity but to be able to loosen the binds between the things or situations and our interpretations of them.

Links to Action Research

One of the first similarities between phenomenology and action research is that neither is a set prescription for doing research or engaging with the world. Both are 'orientations' through which knowledge is created. Phenomenology reawakens people to the wealth of knowing available through their experience of phenomena in their everyday circumstances.

Similarly, action research embraces a number of different research methods which at their heart are pragmatic and grounded in our experience of the world, rather than abstract thoughts about it. For both, the lifeworld is where research happens, and the subjects for research are practical and relevant to human beings as we live our lives.

Both approaches place the researchers themselves at the centre of the endeavour to develop knowing. Meanings are absolutely essential and proper aspects of the research process. Both also recognize the interplay of subjectivity and objectivity in the way in which we come to know. In a later, published version of his lecture 'The Crisis of European Science' (1970), Husserl famously wrote of the 'enigma of subjectivity' and suggested that our knowing of the world is only possible because there is a world to know, once again indicating the central role intentionality plays in consciousness. Similarly, the commitment which action research makes to first, second and third person knowing is indicative of its recognition of the interplay of subjective and objective modes as being necessary for knowledge to be of the most value.

Within a world dominated by a scientific paradigm that places its primary value on objectivity and abstraction, action research stands bereft of a philosophical footing without phenomenology. In turn, action research provides phenomenology with a sympathetic mode of research through which knowledge developed from the lifeworld can be rigorously achieved.

PHILOSOPHY OF SCIENCE

As the name suggests, the philosophy of science is the branch of philosophy that focuses on the sciences. It asks questions such as ‘What is the nature of scientific knowledge?’, ‘What does it mean to know science?’ and ‘What are the theoretical bases for the methodologies of science?’. Philosophers of science raise questions about the ontological nature of science (e.g. What is reality?), the epistemology of science (e.g. What counts as knowledge?), the methodology of science (e.g. How is knowledge generated and acquired?) and the values of science (e.g. How do beliefs about what is worthy affect our conceptions about knowledge?). Given the breadth of this field, it is necessary to restrict this entry to those aspects of the philosophy of science that are most pertinent to action research—the epistemology and methodology of science. To narrow it further, this entry will focus on the dominant contemporary theoretical framework for the practice of science, post-positivism.

Post-Positivism

Post-positivism is best understood by comparing it with positivism, which was the dominant paradigm in the sciences through much of the twentieth century. Inherent in positivist thought is the assumption that there is a knowable real world independent of human observation. As such, positivism is a foundational epistemology. That is, it seeks to base all knowledge claims ultimately on unquestionable facts. These facts can be either logical or empirical in nature. While facts based on logical arguments may at first seem attractive, even the most carefully argued logical system is open to challenge in several ways. For example, although the facts of Euclidean geometry are based on intuitive axioms that appear to be reasonable and unquestionable, it turns out that other highly logical and reasonable geometrical systems can be developed from different axioms. In addition, Kurt Gödel, in his incompleteness theorem, demonstrated that any one logical system fails at some point because it can generate new ideas that go beyond the realm of that system. Possibly, most important is the fact that what may seem reasonable to some people may not seem so to others.

To positivists, the foundation of scientific knowledge can also be empirical. According to this view, scientific knowledge is derived only from observations of the natural world that can be measured in some way. As it turns out, there are practical and theoretical reasons why this is not possible. First, it has been demonstrated that perception is theory-laden. Humans observe the world through the lenses of how they already understand

the world. For example, as Donna Haraway has pointed out, after women entered the field of primatology, they saw co-operation and kinship in primate behaviours where male primatologists had seen conflict. Second, the development of truth statements from observations can only be done through induction. However, it has been shown that induction can be fallible. Simply put, what has been is not always what will be. A simple example of this is that until Europeans saw black swans in Australia, they believed, based on their observations of swans in Europe and North America, that all swans were white. What this shows is that it cannot be proven to be true from the countless observations of only white swans—in other words, through induction—that swans are always white. Tied to the problem with induction is that multiple theories can be used to explain any set of observations. This fallibility of induction is what led Karl Popper to reject the idea that hypotheses can be proved and instead to argue that researchers ought to seek ways to disprove their theories. Third, scientific knowledge is a web-like structure of many beliefs. A belief that is shown to be untrue empirically can be modified by adjusting other beliefs and, therefore, retained. This aspect of science is an integral part of what Thomas Kuhn has called ‘normal science’, which is done within paradigms. While there are times when new evidence causes the rejection of an existing paradigm and leads to the acceptance of a new one (e.g. the move from a geocentric to a heliocentric model of the solar system), it is more common to find ways to adjust the existing network of scientific beliefs than to jettison it. This is similar to Jean Piaget’s notion of assimilation. Finally, science, like any other human activity, is social. Individual scientists do not have their own paradigms; paradigms are part of the beliefs of a community of scientists. It is that community that decides through formal and informal epistemic authorities, such as journal review boards, whether the research findings ought to be accepted as scientific knowledge. In addition, it has been shown in numerous sociological studies that the practice of science is affected by political and economic factors, as well as gender and ethnicity. D. C. Phillips and Nicholas Burbules in their book *Postpositivism and Educational Research* (2000) provide a thorough discussion of the problematic nature of the foundational epistemologies discussed above.

Post-Positivist Epistemology

Post-positivism as an epistemology came about in response to the shortcomings of positivism. One of its most important characteristics is its rejection of foundationalism. To the post-positivist, neither experience nor reason can serve as a fundamental basis for

knowledge. As a result, all knowledge is conjectural. This conclusion was arrived at by the work of scholars such as Popper, Kuhn and Sandra Harding. Popper argued that because scientific knowledge cannot be established via induction, the best that we can do is to try to develop tests that try to disprove theories. Kuhn in his seminal work *The Structure of Scientific Revolutions* (1996) demonstrated that scientific theories are the products of the times in which they are developed. As such, scientific knowledge claims are evaluated by people, who do so from various standpoints, as was demonstrated by Harding and other scholars.

The conjectural nature of scientific knowledge has led some to conclude that because truth is not absolute, all knowledge is relative and there are multiple realities. Post-positivism rejects both of these conclusions, seeking a third place between absolute truth and 'anything goes' relativism by asking whether a knowledge claim is *likely* to be true rather than whether it *is* true. This conception of truth can be found in John Dewey's idea of 'warranted assertability'. In it, he replaces the idea of knowledge with that of knowing and merges truth with inquiry. That is, it is the engagement in inquiry that provides us with the warrants that allow us to assert that a knowledge claim is likely to be true. It is important to note that Dewey suggested that there is little or no difference between the warranting of scientific knowledge claims and other types, such as those that are more aesthetic. What inquiry entails is dependent on the norms of the discipline or practice within which the knowledge claim is to be made. Modern science has developed norms of inquiry that are expected to be followed by the epistemic authorities of its different fields.

Post-Positivist Scientific Practice

To post-positivist scientists, the norms of practice that lead to warranted assertability are obvious. Scientific knowledge claims are evaluated based on the evidence made available and the arguments that are based on that evidence. For the natural sciences, the evidence is produced by observations and measurements that often are the result of controlled experiments but may also come from careful observations and measurements of the naturally occurring world. The latter is most often seen in the field sciences, such as geology, ecology and astronomy, in which controlled experiments are impractical or even impossible. It is also important to note that scientific inquiry can be deductive in nature, often referred to as theoretical science, which argues from and may question existing theories. A community of peers that makes up the epistemic authority evaluates both the evidence and the arguments. The evidence is evaluated primarily by critiquing the ways

in which it was developed. Did the researcher follow careful laboratory procedures? Were the samples kept isolated? Were the instruments adequately calibrated? Were the standard methods of the field followed? It is also evaluated by determining whether it makes sense relative to existing, already published evidence. In the sciences, the argument is often developed using mathematical methods including statistical analysis and by developing mathematical models. Is the mathematics appropriate for the analysis? Are the proper variables selected and isolated? Does the model include all relevant factors? In all cases, the quality of the evidence and the arguments are checked against the existing literature in the field. When all of this is done, including the consideration of counterarguments and negative analyses, we can answer the questions 'Are the scientists' assertions sufficiently warranted?' and 'Are the assertions likely to be true?'. Inherent in all of this is the role of professional judgement. Scientists employ it when deciding what to investigate and how and what warrants should be employed to support their arguments. The community of peers also uses professional judgement in determining whether the warrants sufficiently support the knowledge claims.

Post-Positivism and Action Research

Action research as used in this volume refers to a family of approaches that has as its goal to address organizational, community and social issues while paying close attention to who experiences them. In addition, the 'action' in action research is seen to be liberating. Therefore, it could be said that action research seeks to improve what Hannah Arendt called the human condition. This goal is highly dependent on the values of the researchers and the stakeholders associated with the research. Therefore, when we turn to the application of the philosophy of science to action research, it is necessary to raise the issue of the place of values in science. Again, researchers look at post-positivism to understand the relationship between values and the warranting of knowledge claims. They begin by noting that science is not value-free. The practice of science is a human endeavour, and scientists, as human beings, are influenced by the norms and practices of their communities. Therefore, their personal political and social belief structures, those shared by the members of their scientific community and those of their wider community all influence their practice. That said, post-positivist thought distinguishes between epistemologically relevant and irrelevant values.

Epistemologically relevant values are those that are appropriate for the way in which knowledge is warranted in the field. In post-positivist views of science, these include the valuing of well-thought-out and

well-planned studies, the replicability of investigations and the use of standard instruments and validated methods. When these values are not adhered to, the epistemic authorities of science, such as peer-review panels, eventually recognize that the science was done poorly and that the knowledge claims are insufficiently warranted.

Epistemologically irrelevant values are those that ought to have no role in the warranting of knowledge and may lead to what would be recognized in the field as ‘bad’ science. Within the scientific community, there are what have become standard stories that illustrate this, such as Paul Broca’s brain studies and Trofim Lysenko’s genetics. In both of these examples, values tied to ideologies external to the scientific community were negative influences—in the first, racism and sexism and, in the second, Soviet Marxism.

Unfortunately, the distinction between epistemologically relevant and irrelevant values fails to take into account those human values that shape the scientific enterprise but are not tightly connected to the warranting of knowledge claims. These values are exposed when we attempt to answer the question ‘What is the value of the research?’ While there are those who believe that scientific research can be done solely for the sake of generating new knowledge, the mythic nature of this belief becomes obvious, for example, when one considers that the US National Science Foundation requires all grant proposals to address the ‘broader implications’ of the research. Not only does this make it explicit that the purpose of science is more than knowledge generation, it also implicitly calls attention to the fact that the evaluation of proposals, which is, of course, a decision about funding, is done in relation to American values. Post-positivism recognizes this way in which values are a part of science and suggests that decisions such as which projects should be funded should be made by as broadly representative a group as possible, to the extent of accepting and encouraging the type of representation that can result in what Harding calls ‘strong objectivity’. This suggests that from a post-positivist view of science, action research can respond to the purpose of the improvement of the human condition as long as the values inherent in what counts as improvement are subjected to review by a diverse body and as long as researchers pay attention to epistemologically relevant values while ignoring those that are irrelevant.

Post-Positivism and the Practice of Action Research

Any discussion of the relevance of a post-positivist view of science to the practice of action research must first acknowledge that action research is a wide and

varied field. While some engage in action research from a post-positivist perspective, it is practised in many fields using different methodologies based on diverse conceptual frameworks. Therefore, it is impertinent to suggest that all action research ought to be scientific as defined by post-positivist philosophers. Although some, if not many, action researchers would be put off by the idea of making their methods more scientific, few would argue with the notions that observations are theory-laden, that facts underdetermine conclusions, that values affect the choice of which problems to address and which methods to use and that a broad group of researchers and other stakeholders need to participate in the process of evaluating these choices and the arguments and conclusions of the inquiry. Given that these are the basic tenets of a post-positivist view of science, post-positivism could be used as a basis for suggestions as to how to increase the warranted assertability of the outcomes of action research.

This would be done primarily by action researchers making explicit in their reports what they actually did. While this may seem obvious, it is often omitted in discussions of the quality of action research. For example, Hilary Bradbury and Peter Reason suggest that an action research study can be evaluated by examining the involvement of participants in the research, its practical outcomes, how theory is connected to participants’ experiences and whether it increases ways of knowing, whether its purposes are significant and, finally, how it helps build new infrastructure. While all of these criteria are important, there is no call for the action research reports to detail what was actually done. Action researchers could also provide clear and detailed descriptions of how they construct their representations of their research from their data, which are in some respects their arguments in support of the outcomes of their action research.

In post-positivist views of science, it has been acknowledged that theories are connected to other theories through a relational network of ideas. That is, any possible explanation does not stand alone. When action researchers consider how they understand or explain their results, they could see how their understandings and explanations relate to and connect with what others have found in their field. Scientific arguments are also evaluated on how well they take into account a variety of data sources and whether alternative explanations are considered. In action research, we see this being done through the use of triangulation, the exploration of multiple ways to represent their data and a critique of all possible representations, including the ones that are favoured.

The ways in which values are looked upon in post-positivism also has implications for the practice

of action research. Action researchers can be aware of the relevant and irrelevant values that may affect their work. Some of these would be epistemological and would depend on the features of the theoretical framework that guides the research. However, there are others that go beyond epistemology and relate to the improvements in the human condition that the action researchers seek. Therefore, the warrant of the outcomes of action research could also be asserted by demonstrating how they lead to those improvements, whether they are in the individual, in the organization or in the community. It is important to note that the post-positivist would not be satisfied with the claim that 'it is true because it works'. The warrant would instead be in an explanation or theory of why it works. In addition, that theory would need to be useful for understanding other situations and be subjected to critique. This last suggestion reminds us that action research, like other research according to post-positivism, needs to be responsive to some type of implicit or explicit procedural authority. For the most part, it is explicitly in guidelines for research and publication and more implicitly in the review process for practitioner, professional and research peer-reviewed journals; conference papers and funding proposals and criteria for the awarding of degrees. As noted above, there is a role for professional judgement in both warranting one's results and the evaluation of these warrants by others.

In summary, much of the recent work in the philosophy of science has led to the rejection of the tenets of positivism. The result is a post-positivist view that acknowledges that science is an enterprise that cannot produce infallible truth. This conclusion has been reached both because of logical inconsistencies in a positivist framework and extensive work in the sociology of science that has demonstrated science to be a very human endeavour that is influenced by all aspects of the social world. That said, post-positivists reject the conclusion that because science is fallible, the search for truth ought to be abandoned. Instead, they have suggested methods that can be used to help distinguish between more and less likely explanations. It is these methods, discussed above among others, that could be used by action researchers to similarly support the outcomes of their work.

PHOTOVOICE

Photography has become one of the most ubiquitous forms of communication in the twenty-first century, given the predominance of the visual in Western culture, the proliferation of visual media (e.g. ads, TV and the Internet) and the increasing accessibility and globalization of digital visual technologies. It is thus understandable that photographic tools would become central to participatory processes of action research. In particular, for projects that aim to engage marginalized populations in challenging oppression and developing both the personal and the collective capacity to act for social change, photography can offer an alternative form of representation, an active process of participation and a powerful expression of experience and social issues. Two photographic practices have emerged as popular tools in participatory research projects: Photovoice and Digital Storytelling. The latter is discussed in a separate entry.

Photovoice puts cameras in the hands of those who traditionally might have been identified as the 'research subjects', offering them an opportunity to be active participants in the research process, inviting them to 'voice' their experiences, perspectives and analyses through the photographs that they take. By 'shooting

back', ordinary people democratize the visual media and challenge the role of 'experts' and 'professionals' in the arts, research and education.

Historical and Epistemological Roots

The context within which photography was invented in the mid nineteenth century shaped its early use and impact. Developed by wealthy Europeans in the midst of the colonial period, cameras were initially used to document privileged lives and foreign travels to exotic lands, focusing on 'the spectacle of the other'. They became tools in the racialized classification of humans under European imperialism, reinforcing notions of scientific racism. Photographs also soon replaced drawing in the rising role of advertising to promote industrial capitalism and the consumer culture. The technology of early cameras made them awkward, expensive and inaccessible to ordinary people; they were clearly the domain of the elite and the professionals.

The capacity of photographs to show actual traces of reality also fed dominant epistemologies of positivism and the elevation of the 'objective' nature of reality promoted by Western science. Photographs were used as evidence, and there was little awareness of who was behind the camera, the photographer's perspective or interests. In the early twentieth century, reformist photographers such as Jacob Riis capitalized on this objective power of images to document the horrific living and working conditions of new immigrants to the USA; his aim was to raise public consciousness about poverty and catalyze social and political action. The Farm Security Administration photographers in the 1930s and 1940s had a similar mission: to document the real conditions of poor communities in the midst of the Depression; these classic social documentary images became emblematic of social inequities and were used to press for social reform. But the cameras remained in the hands of the professionals, the practice required considerable financial support and training and the subjects did not benefit from their images.

Photographers' claim to objectivity was debunked in the latter part of the twentieth century by postmodern thinkers and artists, who vigorously challenged the 'objectivity' of positivist Western science and any notion of 'truth' that photographs could portray. Rather, they framed photos as frozen moments reflecting the subjective 'point of view' of the photographer and particular regimes of truth. While for some, this recognition spelled the death of documentary photography, for others—in both the art world and the world of social action—the acknowledgement only expanded the scope of the practice; *Mirrors and Windows*, a pivotal 1978 exhibition at the Museum of Modern Art, embraced both the artist's sensibility (mirror) and the

world she explores (window), or the subjective and the objective power of photographs.

Within the world of social research, there was also a developing sense of the self-reflexivity of the post-positivist researcher. Early developments of participatory research, influenced by the popular education pedagogy of the Brazilian philosopher Paulo Freire, encouraged researchers to acknowledge their non-neutrality and their own power in terms of social identity, organizational identity and political identity. The recognition that all research is ideological and reflects power dynamics led to new tools that attempted to address the inequities between the researcher and the researched. An international network of participatory research within adult education, techniques developed by development practitioners in Participatory Rural Appraisal projects and the global emergence of Participatory Action Research (PAR) all aimed to democratize the research process while also integrating research, education and action.

The democratization of research tools drew naturally on community-engaged artistic practices such as popular theatre, music and the spoken word and, in multiple forms, the use of photographs and video. The early Participatory Research Network of the International Council for Adult Education, for example, involved literacy teachers in Nicaragua and English as a Second Language (ESL) students in Canada in producing photo-stories, based on the daily lives and struggles of the students and appropriating a popular cultural form more common in Latin America and the Mediterranean countries, the *foto-novella* (a kind of soap opera in comic book form). This process built explicitly on Freire's codification of 'themes' of the students' or research subjects' lives, but the photographic production process was still in the hands of the researcher/educator.

The social upheavals of the 1960s also gave rise to experimentation with participatory photography and filmmaking. Appalshop in the USA and the Challenge for Change programme of the National Film Board not only produced socially critical films but also involved grass-roots communities in their production; marginalized youth were taught to produce their own visual statements. Committed social photographers such as Wendy Ewald gave cameras to Appalachian youth to document their daily lives and counter the negative stereotypes perpetuated by the dominant media and social welfare programmes.

Within the academy, in the later twentieth century, there was also a critical rethinking of both research practices and the use of photographs. Subfields of visual anthropology, responding to anti-colonial critiques, and visual sociology, influenced by post-structuralism, organized associations and conferences focusing on visual research practices. For activist scholars, influenced

by feminist, anti-racist and indigenous methodologies, the participatory use of photographs and video offered a new way of honouring the voice of the research subject, troubling historical power dynamics and promoting collaborative knowledge production. They depended less on verbal or literacy skills and led to other ways of knowing; arts-informed research was slowly recognized in an academic context that has historically privileged text-based learning.

The other major influence on the democratization of photo-based research has been the accelerating development of digital visual technologies. Not only are cameras more accessible, more affordable and of higher technical quality, but the evermore ubiquitous cell phone takes pictures. Cameras are thus at almost everyone's fingertips, facility with digital media is equated with citizen participation and the possibilities seem endless. The Internet and other social media are overflowing with creative visual productions coming from the ground up. The ease with which images can be shared on the Internet broadens both the scope and the impact of these tools; local stories can be shared across the globe, linking people, projects and political actions.

The Practice of Photovoice

Origins and Influences

Though participatory photography in research has a long history, the origin of an explicit practice called Photovoice is most often associated with the work of Caroline Wang and her colleagues in health research, starting with a pioneering study in China in the 1990s and now widely adapted for projects with marginalized populations addressing all kinds of social inequities. Wang identifies as theoretical and practical influences Freire's use of 'codes' in processes of conscientization, feminist theory's acknowledging the subjective (the personal is political) and making visible the invisible and the participatory practices of early community photographers such as Jo Spence in the UK and Wendy Ewald and Jim Hubbard in the USA. Wang associates Photovoice with PAR, emphasizing the empowering process of community people documenting and reflecting on their communities and the power of these images to influence individual and community action. She suggests that the technique can be used for different purposes—from specific processes such as participatory needs assessment, asset mapping and participatory evaluation to the deeper goals of developing community capacity to act and to influence policymakers.

Phases

Photovoice projects usually follow three major phases: preparation, production and use. The first

phase includes recruiting a target audience of policymakers and/or community leaders; selecting Photovoice participants, facilitators and photographer mentors and discussing the Photovoice concept and method, including issues of ethics and informed consent, before training participants in the technical use of the camera. In the production phase, participants are given sufficient time to take photos, sometimes around an initial suggested theme related to the specific research; emphasized in this stage is the 'voice' side of Photovoice: group discussion and interpretation of the images. Participants may be asked to select one or two significant photos, then to frame stories around the photos, following a Freirean decoding process, which moves from collective description of the images to connecting them to their own experiences, codifying them into themes, exploring the root causes of the problems represented and proposing action for change. The third phase involves selecting a format to share the photographs with the community and with policymakers and community leaders; if these relationships have been established from the beginning, there is a greater likelihood that the images will be fed into a more public policymaking process.

Examples

The technique has been used globally and for a wide range of issues. Wang's early research in rural China in the 1990s trained 62 village women to document the conditions affecting their health, such as lack of access to clean water; the photos from their participatory needs assessment became a catalyst for action, making the issue a priority for community leaders. Wendy Hussey involved five self-identified female-to-male transsexuals in the USA to examine their experience in accessing health care, to document the needs of the transgender community and to recommend policy changes and educate providers; they collectively identified six themes from their dialogue around the photos and insisted on being at the policymaking table, as visible agents for change.

Ethical Issues

Critical to any discussion of Photovoice are the ethical and political issues raised by its use. First of all, with the aim of social change, the process is explicitly political, and there are always power dynamics at play between Photovoice participants from marginalized communities challenging inequities, the project researchers/facilitators and the community leaders and policymakers they are trying to influence. Given that photographs cannot ensure anonymity, careful attention is given to ethical procedures of informed consent by participants, photo release forms by their subjects

and a consent form if images are to be published. A group discussion of ethics is essential, brochures and letters explaining the project are recommended, and participants are encouraged to give photos back to the people they have photographed. In some cases, honoraria are offered to participants or to those whose images are published, though remuneration can also affect the dynamics.

Limitations and Critiques

Critics have charged Photovoice projects with being tokenistic, creating false hopes and being naive about the political struggles needed to address deeply structural issues at the root of many problems documented by participants. While these critiques can be made of any PAR aimed at social change, the use of photos can exacerbate classic tensions between product and process, aesthetics and ethics, private and public, individual and collective, outsider and insider, ownership and use and education and action. In a culture that is enamoured with technology, there is also the danger of a kind of technicism, where the tools trump the content or process.

Often its success depends on the particular purpose of the project, whether it is mainly to empower participants within a community or if it is to have a broader policy impact. There are also questions about who initiates and leads the process, as the facilitator is never neutral and participation is never completely equal. Practitioners offer tips to facilitators about the importance of creating a climate for respectful dialogue, acknowledging their own non-neutrality while also not imposing their own agendas, adapting to the context and rhythms of the participants and being willing to learn from mistakes. The ubiquity of cameras and photographs in the digital age ensures that various practices of Photovoice will continue to emerge in diverse contexts, feeding the democratization of research and education, as well as a growing community media movement.

PHRÓNĒSIS

The word and concept *phrónêsis* is Greek. Its traditional rendering in English is ‘prudence’, from the Latin *prudentia*. Currently, however, ‘practical wisdom’ or ‘judgement’ is more common. The historical source for the current concept of *phrónêsis* is Aristotle (384–322 BC), in particular Book VI of his *Nicomachean Ethics*. After a brief review of some recent attempts to apply the concept in contexts of social research and professional practice, the following text presents the role and content of *phrónêsis* in the thinking of Aristotle.

Rediscovering Phrónêsis

In the twentieth century, the specifically Aristotelian concept of *phrónêsis* has been the explicit starting point for both Martin Heidegger’s phenomenology and Hans-Georg Gadamer’s hermeneutics and for trying to find ways of conceptualizing knowledge and understanding of human and social relations, alternative to the modern period’s dominant attempts at transferring models of theory, data and ‘applied’ knowledge from astronomy, physics and other natural sciences to the study and practice of human individuals, culture and society. Since the ‘relaunch’ of the concept, and as part of its gradual re-appropriation, many have attempted to apply, adjust and integrate Aristotelian *phrónêsis* into professional and managerial practice, modern education and social research. Most interpretations

separate *phrónêsis* from two other major knowledge forms in Aristotle in order to emphasize and cultivate *phrónêsis* as an independent alternative to *epistêmê* and *téchnê*, in other words to ‘science’ and ‘technology’ or ‘technique’. *Phrónêsis* is seen as a form of rationality connected to *praxis*, which in turn is interpreted as approximately our everyday or professional activities, in contrast to a predetermined formalism of encroaching requirements from science and technique. Based on a close reading of the *Corpus Aristotelicum*, the author criticizes widespread tendencies in the ‘applied’ appropriation of *phrónêsis*. *Phrónêsis* cannot be reduced to normative, applied social research and counselling within a modern division of labour between researchers and the researched or between professionals and clients, and *epistêmê* cannot be equated with modern science. There are differences both in kind and of degree *within* the Aristotelian *epistêmê*, and theoretical and practical philosophy cannot really be segregated. Theory should not be abandoned but differentiated and redefined. The concept of *praxis* as the foundation for *phrónêsis*, on the other hand, is more specific than our everyday or professional activities. It is also more specific than most modern hybrid concepts of ‘practice’. Different aspects of *praxis* must be distinguished even in its specialized Aristotelian sense.

Phrónêsis as an Intellectual Virtue or Excellence

According to Aristotle, *phrónêsis* is one of several ‘intellectual virtues’ or ‘excellences of the mind’. A virtue is a *hêxis* or *habitus* (Latin), which means an acquired ability, skill, habit or disposition and a proclivity for acting and feeling in certain ways, resulting from practice, exercise or habituation. A *habitus* can be either deficient or adequate in relation to standards inherent in its activity, but virtue is by definition the best *habitus* within its specific field or kind of activity. The activity of the intellect—in other words, thinking—consists in the use of reasoned speech or *lógos*. Its *lógos* character makes it intellectual. Its ability to use *lógos* correctly makes it virtuous. The common task of intellectual virtues is to attain truth by affirming and denying, as Aristotle puts it. The ‘true’ and the ‘false’ as species belong to the genus of validity in general, together with ‘right’ and ‘wrong’, ‘good’ and ‘bad’, ‘expedient’ and ‘harmful’, ‘beautiful’ and ‘ugly’ and other validity dimensions inescapable for *lógos* users. In Book VI of the *Nicomachean Ethics*, *phrónêsis* is defined in relation to several other intellectual excellences and faculties and by connecting it to *praxis* (pp. iii–xiii). *Sophía*, or ‘theoretical wisdom’, encompasses all the virtues, both intellectual and ethical. It is part of virtue as a whole, as ‘head’ of the virtues.

Sophía is composed of two intellectual virtues immediately ‘below’ it: *nous* and *epistêmê*. Both of these relate primarily to levels and aspects of things that remain the same through change. *Nous* moves ‘upwards’ inductively from particulars and grasps basic principles, while *epistêmê* (‘science’) moves ‘downwards’, reasoning deductively from basic and primary principles. *Nous* usually translates as some kind of intuitive intelligence but is also considered to be more reflective. Indeed, unfolded *nous* and the activity of *noêsis* may very well be interpreted as being inductive and searching dialogue or dialectics, in parallel to how Aristotle defines the unfolded activity of *epistêmê* as deductive or didactic demonstration. The previous virtues are not only intellectual but also theoretical in being non-intervening, non-normative and non-prescriptive and merely descriptive, distinguishing and analytically directed at stable elements, aspects or levels of things and activities. Other intellectual virtues such as *téchnê* (craft competence) and *phrónêsis* are non-theoretical but intervening or prescriptive, dealing with what can change or be brought into existence, depending on what we ourselves do or do not do. They concern things that we ourselves can control, in other words decide on, choose, initiate, change, develop or stop, so that the variation depends on us.

Phrónêsis as Deliberation

Phrónêsis, then, is a way of using *lógos*, a way of reasoning or arguing about what to do. In the Aristotelian scheme, there are several ways of reasoning. A finished science is deductive, research or unfinished science is dialectical or dialogical and *téchnê* is calculative. *Phrónêsis*, however, is deliberative (*bouleutikê*); in other words, it searches for and weighs arguments for and against on what to do, here and now, considering the particulars of the situation. But analyzing and understanding the particulars of the situation is not peculiar to *phrónêsis* alone. What Aristotle calls *súnêsis* or concrete understanding does this too, but without being normative and prescriptive. *Súnêsis* is merely critically distinguishing—a form of dialogical discretion. It is a theoretical virtue. Deliberation as such is not peculiar to *phrónêsis* alone either. Cleverness or smartness (*deinôtês*) deliberates as well, but for non-virtuous ends (e.g. arbitrary, tactical, strategic, egotistical, evil, etc.). As a deliberative ability, *phrónêsis* is inherent in the other ethical virtues (e.g. justice, friendship, courage, etc.). The ‘non-intellectual’ ethical virtues provide the ends, while *phrónêsis* deliberates about ‘means’, which is why we cannot be prudent (*phrónimoi*) without being (ethically) good. But in turn, the non-intellectual virtues are developed primarily through *praxis* and critical dialogue. Cleverness (*deinôtês*), concrete understanding

(*súnesis*) and ethical virtue (*êthikê arête*) are in a way integrated parts of *phrónêsis*, which transforms the parts in the integration process. An ethical virtue is a habituated inclination (*habitus*) to act and feel ‘correctly’, but not only according to right reason. Single virtuous acts can be done in a formally correct way from mere habit, by chance, by mechanical rule following or under the influence of others (by following orders). To be truly virtuous, acts must spring from a virtuous disposition and be done with the right reason or justification, according to Aristotle, and *phrónêsis* is right reason in these matters.

Phrónêsis as an Ethical Virtue or Excellence

Most of the intellectual disciplines and virtues are instruments or means that can be used for both good and bad ethical purposes. But *phrónêsis* in itself is also an ethical virtue, in other words a virtue of character. Apart from theoretical wisdom (*sophía*), the other intellectual virtues, being merely rational powers, are not given intrinsic ethical value. In such technical and instrumental virtues, a voluntary error is not as bad as an involuntary error. Making a deliberate mistake in singing or playing an instrument may merely prove your mastery of the art. But in the ethical virtues, a voluntary mistake—being deliberately unjust, unfriendly and so on—is worse than the involuntary mistake of being unknowingly unjust or unfriendly. Also, forgetting a technical skill is not generally considered blameworthy, but forgetting the ethical virtues is. Forgetting or making a mistake concerning *phrónêsis* is. *Phrónêsis* deliberates about how one should be just, fair, friendly, caring and so on in relation to other people here and now, people with quite different needs and wishes, all things considered, but still respecting their autonomy as thinking minds and wills separate from ours. *Phrónêsis* has to heed appearances through the different opinions and desires of different people at different stages, phases or situations of life, and how one identical, accidental property of something may appear pleasant, harmful, indifferent or simply instrumentally useful to different people. Hence, there cannot be any *téchnê* or precept for dealing with it. In addition, *phrónêsis* cannot be used to deliberate instrumentally about how to make anyone simply serve our purposes. Doing that would reduce it to *téchnê*. *Phrónêsis* does not try to manipulate or merely to persuade or seduce. It must present its own thinking and reasons for deciding and acting in certain ways as openly and as transparently as possible to the mindful judgement of others (as to itself), trying to show and convince, making them *see* but still respecting their autonomy. *Phrónêsis* must consider where others are, emotionally, intellectually and in their skills and attitudes, in trying to find the

right thing to do, but it cannot use these circumstances manipulatively in setting through some hidden agenda without ruining itself *qua phrónêsis*. It must know how to deal with egotistical, strategic, manipulative behaviour in others without itself becoming like this, but also without simply being subdued by it and letting such behaviour prevail in others and in general.

This is why and how *phrónêsis* is both ethical and intellectual: (a) because one would blame someone for forgetting or neglecting to do these intellectual exercises in dealing with others, treating everyone exactly the same regardless of circumstances, preconditions and so on; (b) because abstaining consciously and voluntarily from deliberating for and against on what to do would be considered an ethical deficiency and (c) because one would blame someone for deliberating merely cleverly for other—unethical—purposes in dealing with others or even manipulating others technically.

Phrónêsis as Understanding and Catching the Right Moment (*Kairós*)

Defining the right thing to do in general and unqualified ways, as general rules or commandments, becomes too simple, unconditional and absolute. Novices and amateurs with a shallow and superficial understanding of what they are dealing with think and talk in too general terms. Simultaneously, lacking the ability to analyze and deliberate autonomously, they depend on general rules. Such moralists do not adjust to the *kairós*—doing the right thing, for the right purpose, in the right way, to the right people, in the right amount, at the right time, in the right place and so on—but prescribe doing things ‘always’ or ‘never’. But *phrónêsis* is situated and considerate. It takes its own circumstances and conditions of performance into account. Following a rule always, dogmatically or mechanically, is not praxis because it does not use *phrónêsis*. Deliberation distinguishes *phrónêsis* in its relation to praxis. Someone deliberating presupposes independent minds like himself acting. Deliberation necessarily relates to independent minds in taking and giving counsel, since advice and admonitions must be understood. *Téchnê* and *poiêsis* do not presuppose independent minds or any consciousness at all among the receivers of their technical treatment. They presuppose the opposite. Technical causes do not have to be understood in order to work.

Phrónêsis Differs From Rhetoric and Syllogistic Reasoning

Phrónêsis differs from rhetoric. *Phrónêsis* searches openly for the best thing to do, weighing arguments for and against. Rhetoric is not primarily deliberative

but persuasive and seductive. In being open-ended regarding its concrete conclusions, *phrónēsis* is not deliberately persuasive, while rhetoric is deliberately persuasive or seductive for any kind of purpose. But in arguing persuasively in favour of predetermined and favoured decisions as conclusions, it is not very deliberative. True deliberation is open-ended. Rhetoric delivers the tools for conducting a debate where the point is to beat an opponent and to win an audience. It operates persuasively towards the audience and in agnostic ways towards its opponent. Aristotle speaks of rhetoric as a *téchnē*. Practical reasoning is sometimes reduced to practical syllogisms, in other words to a form similar to the following: Two premises, one universal (normative major), as, for example, 'All sweet things ought to be tasted', and one particular (descriptive minor), as, for example, 'This particular thing is sweet', will lead to the individual tasting this particular thing, if nothing stops him. But *phrónēsis* cannot be reduced to practical syllogisms. The most important aspect of *phrónēsis* is that it deals with particular circumstances in connection with acting. But the practical syllogism is deficient in leaving out its two most important parts: (1) the analysis of the concrete situation and (2) the deliberation about what to do and how, all things considered. There is no analysis, nor is any deliberation going on, moving through the practical syllogism, only deductive inference through formally identical terms.

Challenging Aspects

There are several controversial aspects of *phrónēsis*, particularly its relationship to general knowledge and to ends and 'values'. Many modern interpreters seem to think that *phrónēsis* is self-sufficient and can abandon theory and general knowledge. At the same time, they seem to think it represents a form of 'value rationality' in contrast to technical or instrumental rationality. Aristotle is quite explicit that *phrónēsis* consists not only (*ou mónon*) in general knowledge but in knowledge of particulars as well (*kai*), since it is practical and has a decision on what to do as its objective. If general knowledge is needed, the question is what kind. There is much general knowledge in the ethical virtues, not only in modern scientific theories. Aristotle also emphasizes repeatedly that *phrónēsis* deliberates the means, while the virtues provide the ends. Sometimes it is also claimed that *phrónēsis* is based on experience, in contrast to science and technique. But the same experience (*empeiria*) forms the base for all of these in Aristotle. Challenges like these complicate claims that *phrónēsis* can be a self-sufficient and independent alternative to *epistēmē*.

Phrónēsis and Action Research

Phrónēsis clarifies an inescapable aspect of professional practice—the analysis and consideration of and the adjustment to concrete situations and circumstances. It is similar to what Donald Schön called 'reflection in practice'. This also makes it clear, however, that *phrónēsis* is primarily a part of professional performance. The critical and analytical reflection 'on practice' was conceived as dialogical by Aristotle and Plato. *Phrónēsis* is clearly a natural part of the well-known cycles of action research, and it clearly belongs to a field of action and knowing relevant for action research, where events depend on what we ourselves do, or do not do, in other words, what we ourselves can control and decide on, choose, initiate, change, develop or top.

POSITIONALITY

Positionality refers to the stance or positioning of the researcher in relation to the social and political context of the study—the community, the organization or the participant group. The position adopted by a researcher affects every phase of the research process, from the way the question or problem is initially constructed, designed and conducted to how others are invited to participate, the ways in which knowledge is constructed and acted on and, finally, the ways in which outcomes are disseminated and published. Following is a description of the outsider and insider roles of researchers and a discussion of the multiple dimensions influencing how researchers may relate to the action research participants.

Insider or Outsider Role

In action research, the concept of positionality is referenced in terms of the researcher's insider or outsider relationship to the community engaged in the inquiry. Kathryn Herr and Gary Anderson in their book on action research dissertations provide extensive discussion on the continuum of insider and outsider relationships. An insider is a researcher or participant who works for or is a member of the participant community, while an outsider (e.g. an academic researcher) is seen as a non-member. Herr and Anderson describe six positions along a continuum:

1. Insider (researcher studies own practice)
2. Insider in collaboration with other insiders
3. Insider(s) in collaboration with outsider(s)
4. Reciprocal collaboration (equal insider and outsider teams)
5. Outsider(s) in collaboration with insider(s) (non-equivalent relationships)
6. Outsider(s) studies

The first five 'positions' are consistent with the foundational principles of action research as a participatory

and reflexive practice that involves researchers and participants in a process of co-inquiry to address identified problems, create change or explore opportunities. Researchers as outsiders (the sixth position) involves gathering data about others as objectified research subjects, a position more typical of traditional research.

Dimensions of Relatedness

Feminist ethnographers are particularly sensitive to the issues of positionality, defined in terms of the degree of relatedness of the researcher to the study participants along dimensions of culture, class, gender, age, religion, sexual orientation, childhood lived experiences and so on. Insider researchers generally have more in common with participants than outsiders along many of these dimensions. Implicit in these conceptualizations of positionality is the notion of power and intentions. The closer the researcher is positioned to the participants, the more likely that there are common expectations, intentions and power equity.

Positionality is multidimensional, and it is not uncommon for the researcher(s) to be closely positioned to the participants on some dimensions and not on others. These disparities can create conflict, changing the process and outcomes of the study. Kimberly Huisman eloquently describes these tensions in her ethnographic study with Bosnian women. She closely identified with her participants as a woman, friend and confidante but found that they were on different platforms in terms of life experience, culture and goals (she was a graduate student completing her dissertation, while her participants were a part of refugee families struggling to create new lives). While Huisman was acutely aware of her outsider privileged status and the multitude of different values and world experiences, she strived to build a collaborative relationship with her participants as insiders—joining culturally where she had values in common as women. In the end, she completed her dissertation work and moved away, further accentuating the differences.

Not only do dimensions of culture, class, gender, age and political or social identity define the degree of commonality between researcher(s) and participants, but these dimensions extend into the values and world view that one brings to the research enterprise, thus influencing what is perceived and understood as knowledge. Accepting that what is perceived in the workplace or social community as reality is socially constructed, positionality will significantly influence the decisions made during each cycle of the research process. An interesting variation on this concept of perspective or world view is offered by Patricia Hill Collins, who describes 'the outsider-within'. She suggests that one's location within the organization

creates different lenses of reality. For example, a small subgroup (e.g. women in a male-dominated workplace) may take on the role of marginalized or expert observers who shape their reality as outsiders (with an outsider's world view) and also their experience as insiders who have a common stake in the outcomes.

Evolving Nature of Researcher Positionality

In action research, positionality frequently changes over time through different phases of the inquiry process. Sonia Ospina and her colleagues drew on Herr and Anderson's typology of positionality to describe their hybrid research design exploring the development of leadership across 92 social change organizations. As the action research project evolved, the researchers discovered that their positionality varied from an 'insider in collaboration with outsiders' to 'reciprocal collaboration', to 'outsiders in collaboration with insiders'. The research team found that positionality varied with regard to control over the research process, the action orientation of the research and the voice represented in the production of knowledge. Despite the best of intentions to achieve reciprocal collaboration, constraints were imposed by external funder requirements, the difficulty involved in negotiating collaborative roles and the localized focus of participants.

Positionality is an important consideration in action research because it not only directly influences how the research is carried out but also determines the prevailing outcomes and results—whose voice(s) will be represented in the final reports or decisions. Ospina, Dodge, Foldy, and Hofmann-Pinilla (2008) noted that the funder's power elevated the position and perspective of the outsiders while minimizing or ignoring the interests of some community participants. In conclusion, researchers must be acutely conscious of the positionality issues and how they will influence the course and reported outcomes of an action research project, continually bringing them to the forefront for discussion with participants and seeking to redress power imbalances that disenfranchise or minimize the voice of key participant groups.

POSITIVE ORGANIZATIONAL SCHOLARSHIP AND APPRECIATIVE INQUIRY

Positive organizational scholarship (POS) is a social science movement and orientation that focuses on the factors, enablers, mechanisms and effects of positive deviance in human organizational systems. The term *positive organizational scholarship* was coined by Kim Cameron, Jane Dutton and Bob Quinn in the early 2000s. The University of Michigan's Center for Positive Organizational Scholarship hosts a worldwide community of scholars who conduct POS-related research.

'Positive' indicates that POS aims to focus on those dimensions of the human experience that characterize exceptional effectiveness, well-being and a virtuous, desired state or capacity. 'Organizational' conveys that POS focuses attention on organization-level phenomena. Through 'scholarship', POS is intended to generate empirically defensible conclusions that can drive evidence-based solutions. POS is one component in a general movement among social scientists and philosophers to understand the positive or highly functional dimensions of the human experience, with parallel research occurring in related fields such as positive psychology, positive organizational ethics, positive organizational behaviour and virtue ethics.

In some respects, POS may be seen as an empirical, positivist counterpart to the constructivist orientation found in Appreciative Inquiry (AI). A foundational premise in AI is that organizations and institutions emerge from socially constructed, enacted images that come to be seen as an objective reality by those who participate

in them. This presumption supports a socio-rationalist approach to the intentional creation of positive change.

Thus, AI and POS arrive at the meaning of ‘the positive’ or ‘the good’ through very different lenses. AI relies on the constructionist notion that organizational reality is subjective and mutable and therefore open to design. Leaders and researchers alike can either choose to accept deficiency-oriented social constructions or foster abundance-oriented appreciative narratives. In contrast, the POS movement aims to explore the meaning of ‘positive’ through replicable, positivist empiricism in the mode of traditional science. POS advocates have intentionally sought legitimacy through the promotion of results-driven scholarship. At first glance, these perspectives might seem somewhat incompatible.

However, POS has helped legitimize and extend AI methodologies and other organization development approaches that claim to encourage positive dynamics in organizations. POS research has generated several theoretical frameworks that may help explain why AI works, providing insight as to how practice can be shaped to create the intended generative effects. Conversely, POS may also be seen as a manifestation of AI’s central, social constructionist hypothesis as applied to the world of scholarship: By focusing attention on questions that address the positive, exceptional dimensions of the human experience, our ability to articulate and enact positive organizational practices is growing.

To date, the connection of POS to action research has been made only indirectly, mostly through AI practitioners and scholars. However, POS is not synonymous with AI, and POS scholarship provides insights that may be of value to the broader community of action researchers, particularly with respect to the conditions that enable action in organizational life.

Indeed, AI proponents have gleaned a number of insights from POS research. These include discoveries related to the role of positive emotions, the function of positive energy networks, the buffering and amplifying of the effects of positive climate, the motivational power of meaning and significance, the significance of high-quality relationships and the imbalance of positivity to negativity in highly functional groups, among many others. The following areas of POS research have been frequently invoked by AI practitioners and scholars.

Positive Emotions

Much POS research focuses on the role of positive emotions in human and organizational life. Positive emotions (e.g. joyfulness, love or appreciation) enlarge the capacity for cognitive awareness. People

can absorb more information, make richer interpretations and engage in more complex thinking when they experience positive emotions. In addition, when people experience positive emotions in relationships, they are less likely to notice interpersonal differences and more likely to empathize with and connect with others. This body of research strongly supports AI practices that encourage generativity by helping people to focus on high-point moments, discuss meaningful experience and engage in playful activities. Such activities evoke positive emotionality, thereby inducing their predicted benefits, including a stronger capacity to engage in conversations that build new social constructions.

Positive-Energy Networks

A positive-energy network refers to the social connections through which positive emotion flows through an organization; a positive energy network indicates the presence of social capital. Positive energy is also described as the impetus for heliotropism, the tendency of an organism to seek sources of energy (i.e. as the head of a sunflower follows the sun). Some individuals in an organization can be identified as ‘positive energizers’, meaning that their acts are perceived by others as creating a positive, energizing impact on the people who interact with them. Positive energizers have an important effect on others. They support, uplift and boost those who are around them, and they exert an enabling, motivating influence. They are often perceived as having virtuous character attributes, such as optimism, integrity, humility and unselfishness. Most important, positive energizers enable others to be positive energizers through a virtuous cycle. One characteristic of high-performing organizations is that their network of positive energizers is three times the size of the energy network in an average organization.

Positive Interpersonal Relationships

The strength of interpersonal ties between people in organizations is another important enabler of positive change. Positive, high-quality relationships are those that create a ‘generative source of enrichment, vitality and learning’ for both individuals and organizations. Positive relationships are an important enabler of positively deviant outcomes—physiologically, psychologically, emotionally and organizationally. Even short-term, positive relationships can leave a lasting effect. Positive relationships create a conduit for resource sharing and co-ordinated action, which leads to greater organizational effectiveness through the formation of social capital and synchronicity. The scholarship on

positive relationships has interesting implications for AI. For example, a common assumption is that people feel secure in and are motivated by positive relationships when they receive love, support and encouragement from others. However, research suggests that *what people give* to a relationship has a stronger correlation to the outcomes of a positive connection. In AI practice, this effect may be activated through exercises that encourage people to recognize and describe the strengths and capacities they see in others.

Positivity-Negativity Ratio

An oft-cited POS finding is an imbalance favouring the frequency of positive over negative emotional experiences as expressed within high-performance teams and healthy interpersonal relationships. Though the exact dimensions of the imbalance have proven to be controversial, a pattern of imbalanced positive emotions over negative emotions consistently appears across a variety of studies and contexts. This pattern correlates with the propensity of people to form strong, positive connections. AI facilitators and writers have frequently cited such work as justification for the focus on positive questions as a primary mechanism for inducing the conditions that lead to generative dynamics in an organization.

Positive Meaning and Purpose

An important advance in motivation theory is the perspective that people can be more motivated by a sense of purpose than they are by extrinsic rewards, such as purposefulness and experienced meaningfulness. *Purposefulness* indicates that a person aspires to some end state, like excellence or virtue, that provides guidance and direction to one's behaviour. *Experienced meaningfulness* describes the inherent 'significance or meaning' that a person may draw from work itself. Often, work itself can acquire a character that conveys significance or meaning. When people view their work as having purpose and significance, they are typically motivated to perform this work at a much higher level. These theories support the use of and offer an explanation for the effect of how AI's reliance on conversations about meaningful and significant narratives, as well as strengths and values, should arouse the desire for a sense of purpose in people. This may explain why AI seems to create strong commitment in people to implement the changes that they develop through the AI process.

Positive Climate

A positive climate is a collective social state that is characterized by the presence of positive organizational

practices or organizational virtuousness. A positive climate enables people to work through negative or challenging experiences more effectively. Virtuous spirals create an environment in which people deal with setbacks through actions that generate amplifying and buffering effects. Research on positive climate is especially relevant for AI projects in difficult circumstances, such as downsizing, reorganization or mergers. Negative organizational dynamics, if dominant, create a downward spiral in which each setback or difficult moment may contribute to and amplify the stress, anxiety and other forms of negativity that people may be experiencing. AI can help create a pocket of safety in such an environment, in which people can discuss their situation in a proactive, functional and healthy manner. A positive climate activates the positive potential of negative emotions, as positive emotions counter the potentially negative effects of fear, anger, sadness or anxiety. In such a situation, positive social constructions can generate a sense of hope and possibility, allowing for regenerative outcomes.

As illustrated by these examples, POS is an important resource for any applied practice, like AI, that focuses on building or maintaining highly effective organizations.

POSITIVITISM

See Philosophy of Science

POST-COLONIAL THEORY

Post-colonial theory is a critical body of knowledge that questions the dominant ways through which the world is known and how this knowledge is defined. Also referred to as *post-colonial critique* or *post-colonialism*, this body of knowledge is fundamentally premised on the critique of what is seen as Western intellectualism and knowledge hegemony, with its discourses and thought formations believed to be unduly privileged as the mainstream. Spurning what it considers established agendas and radically rejecting accustomed ways of seeing, post-colonialism contends that these are not only rooted in colonial perspectives but that they advance a Western world view to the exclusion of ‘other’, non-Western views—that is, that there are intrinsically ethnocentric assumptions underpinning ‘mainstream’ disciplines which are fundamentally unrecognizing of the values and practices of other non-Western cultures.

Despite the chronological connotation reflected in the prefix ‘post’, post-colonial in this case does not necessarily refer to descriptions of time or periodic shifts, as in ‘after-colonialism’; rather, it is connotative of an adverse theoretical stance or opposing position to what has come to be regarded as the ‘establishment’ or ‘mainstream’ in knowledge formation. In her 2007 article, Brett Christophers defined this as the wide-ranging critique of the ways of thinking, of seeing and of representing the imperialist ‘empire’ which continue to persist in different degrees, long after the dismantling of that empire. In challenging established ways of knowing, it advocates a deconstruction of mainstream knowledge regimes, which it argues are a product of the colonizer’s world view and as such are underpinned by colonial forms of thought and patterns of knowing, and again, it calls for a repositioning of dominant Western discourses in a way that presents these not as totalitarian or universal but, more reflexively, as part of a plurality of knowledges.

Post-colonialism therefore challenges and critiques the dynamics of knowledge creation and argues for an ontological deconstruction of mainstream knowledge formations; in particular, it problematizes how we ‘know’ the world and pushes for an epistemological reorientation with regard to our perception, acknowledgement and validation of ‘truth’. This entry discusses

some of the main arguments and key theoretical concepts that underpin this perspective and will briefly examine its relevance as a possible outlook for future research.

Main Arguments

Post-colonial theorists contend that ‘the world’ has long been viewed through the one-sided ethnocentric lens of the colonizer and that this has been to the detriment and subsequent marginalization of the no less significant world views of the colonized. They hold that the systematic production and organization of Western knowledge in its show of ethnocentrism not only legitimized its privileged positioning as the mainstream but also created an uneven dichotomy in which other, non-Western forms of knowledge were cast in the periphery and, again, that this imbalanced view of the world was due more to reasons of vested economic interests and political control than to unintentional oversight or ignorant omission.

Although conquest and political subjugation had long existed, what appear to have significantly differentiated colonialism in this case were the economic, cultural and ideological dimensions to its operations. New lands were not only conquered and their wealth systematically extracted, but the colonies were subsequently linked to the West in complex arrangements of governance, unfair exchange and commercialization which ensured that they remained economically dependent on the West for sustainability. That is, colonialism not only created structures that facilitated the extraction of wealth from the colonies but also instituted economic systems which ensured a reliance on the West for the sustenance of economic life within the colonies. It therefore sought to impose Western hegemony not only politically but also economically, culturally and ideologically.

Furthermore, it has been argued that the diverse conquests and ensuing subjugation of new territories were captured in subject narratives that underscored the importance of the ‘White man’s burden’ and the various obstacles that had to be overcome to establish a new order of civilization within the new colonies, historical narratives that fundamentally ensconced the culturally tinted world view of the colonizer, particularly of the colonized ‘subjects’, and from which, it is argued, whole new disciplines were born.

According to this view, the colonizer’s quest to ‘civilize’ the ‘other’ did not only require an understanding of the latter’s ‘uncivilized’ world for the former to maintain effective political and economic control but also enabled the articulation of this civilizing cause in subject narratives. These subject narratives, progressively secured in systems of knowledge, not only

presented the colonizer's own culturally tinted view and understanding of the 'uncivilized' and their world but also helped to highlight the many obstacles to the civilizing mission. They would also seek to explain the reasons for these obstacles as well as how they could be sufficiently overcome. In this, however, the voices of the colonized were not considered necessary to this cause and as such were unsolicited and, as Gayatri Chakravorty Spivak notes, have remained dislocated from and incoherent in the mainstream, with their history and 'ways of being' subsequently re-inscribed by the pen of the colonizer, who allegedly 'understood' them and, as such, could represent and speak for them. Crucially, it is argued that this imperialist narrativization of history was progressively secured in systems of knowledge that found initial legitimization in regimes of political control and economic materiality and was subsequently perpetuated through rhetorical means of reiteration. As such, rather than a universal or totalitarian picture of 'truth', these knowledges are considered by post-colonial critics as the product of a rationalized, instrumentalist and individualist Western culture, and such is the thought formation which post-colonialism so fundamentally critiques.

Key Concepts

Post-colonial theory gained much prominence with the publication of Edward Said's influential, groundbreaking classic, *Orientalism*. Published in 1978, this work analyzed Western discourses of Islam and the Middle East and critiqued this as having produced a form of intellectual colonialism which reordered the world along binary frameworks designed to work in its favour; with the West cast as 'self' and the rest of the world classed as the 'other'. In post-colonial discourse, this practice of naming is termed *othering*; a covert process of naming in which the colonizer is projected as the 'all-knowing, civilized occident' and the colonized subject cast simultaneously as that referential inferior 'other', who, as Homi Bhabha observed, possessed an uncivilized reality that was entirely visible to and knowable by the former. Indeed, this 'other' is also sometimes referred to as 'the subaltern'. Originally derived from the Indian myth of 'widow burning', Spivak uses the term *subaltern* to represent the marginalized oppressed status of the historical colonized subject. In this, she describes a part of the Indian population who apparently have been written out of their own history by Western imperialist narratives of conquest and subjugation. Fundamentally, the concept of subalternity draws attention to the plight of the colonized female subject in history as one who is helplessly silent because she is doubly obscured from view—first, in a cultural sense as a female within a traditionally patriarchal society and, again, by the colonial

historical narratives of an imperialist political era in which she is presented as the native 'other'.

In the Indian myth of widow burning, this colonized female subject is silenced because she is unable to properly render her own experience or account of events. She 'cannot speak' to us because knowledge about her is presented through indigenous patriarchal accounts that traditionally obscure the female experience and, again, through imperialist narrativization of colonial history. The concept of the subaltern thus underscores the notion of the Third World subject and is fundamentally critiquing of how this subject is represented within Western discourse. It describes the predicament of the silenced colonial subject, whose voice is systematically foreclosed from formal theoretical formations underpinned by imperialist knowledge hegemony. It is used often in a negative sense in that it paints a picture of intellectual denial, one in which dominant discourses not only misrepresent certain peoples but, in a move that is essentially reductionist, obscure the heterogeneity of their ways of being in the development of Western rational thought. Spivak terms this reductionism 'epistemic violence', argues that there are certain interests at work which intentionally foreclose the agency of the subaltern and concludes that the development of the Western rational subject is itself dependent on the silencing of other, non-Western subjectivities. These post-colonial critics contend that this situation of silencing, oppression and subalternity has persisted in contemporary knowledge creation, and they therefore urge that deconstructive knowledge strategies be adopted in order to be able to reconstruct the subaltern in present-day thought. As such, it is felt that maintaining a post-colonial awareness in the process of knowledge generation is a key way to achieving this.

Post-Colonialism in Knowledge Creation

Presently, mainstream knowledge is still believed to be ethnocentric and largely underpinned by Western intellectualism, which may have failed to acknowledge the existence of a plurality of perspectives. Indeed, it is thought that even the instruments of knowledge creation are themselves ethnocentric. This is because, on the one hand, traditional research is fundamentally designed to analyze cause-and-effect relationships and establish causality, focusing on the researched as passive subjects who must be studied objectively from a distance rather than as relevant stakeholders whose voices are cardinal to the research process and should indeed be heard; on the other hand, post-colonialism has continued to cite the insufficiency of Western epistemological frameworks in grappling with the totality, complexity and heterogeneity of the rest of the world. It is felt that in order to address knowledge

ethnocentrism occasioned by a false consciousness of formerly colonized peoples, researchers should begin to strive towards maintaining a post-colonial awareness and, as Gavin Jack and Robert Westwood have noted, towards attaining a consciousness of subalternity in order to collaboratively engage with the world(s) of the researched in a way that acknowledges cultural and ideological heterogeneity and does not silence or marginalize their voices.

Conclusion

In summary, it is understood that Western colonialism and non-Western resistance to it have very important implications for how we see and know the world. Post-colonial theory decries the universalizing tendency of Western knowledge as being the negative enduring legacy of an imperialist colonial empire, one that has continued to silence and marginalize non-Western subjectivities. It stresses that rather than assume a totalitarian and universalist orientation, Western intellectualism should not only recognize the legitimacy of other, non-Western world views but, more important, should be positioned as part and parcel of a plurality of knowledges rather than as mainstream.

theories or truths. Often criticized as relativistic, postmodernism targets the prevailing values and structures of meaning that persisted through modernism. While postmodernists are not in full agreement and do not regularly and consistently use the term, the common concerns of postmodernism include questions of identities and the formation of the self; truth and representation, especially in images and language, and the work of power structures for social control and marginalization. Postmodernism theory is notoriously difficult, and its texts are often criticized for their opacity, although demonstrating the elusiveness of meaning is part of the point. Postmodernism enjoys a wide purview and is commonly employed within critical theory. It has found particular standing within the arts, literature and humanities, claiming, as proponents do, the world as a 'text'.

This entry covers the historical development of postmodernism as well as several key theorists, their primary contributions and central issues, such as identity, truth and representation and the media. It concludes with consideration of postmodernism's relevance to action research.

Historical Development

As the 'post' indicates, postmodernism is in part a response to the positions of modernism. Some theorists view postmodernism as a continuation of modernism in its pursuit of individual truths and blurring of high and low culture. Others view postmodernism as a distinct divergence or correction to modernism because of its more self-aware contextualization, its more thorough scepticism and the rejection of progression or any foundational truths—individual or collective.

Postmodernism rose in prominence during and following the Cold War decades as traditional structures and institutions of meaning continued to lose standing. Especially in Western Europe and the USA, people increasingly lost confidence in their governments through war and scandals and lost faith in religion as the old cultural traditions for the pursuit of a meaningful life suffered in competition with increased individual freedoms and opportunities, however constrained. These cultural changes occurred at a time when easier travel, increased migration and the expansion of broadcast and interactive media were crumbling traditional boundaries.

The events of September 11, however, signalled to many an end to the rise of postmodernism. The consequences of a relativist view of truth became more problematic in a world where differing versions of truth contributed to terrorist acts. While the blurring of boundaries and the fusion of entertainment and reality that distinguished the attacks were considered the

POSTMODERNISM

Postmodernism is a critical practice of describing and critiquing what proponents view as the fractured experiences of contemporary life. Its position is primarily that of the sceptic in questioning any supposed grand

hallmarks of postmodernism—the news footage frequently was said to resemble that of a Hollywood disaster film—the stakes were far greater than the weight of postmodern theory. Still, postmodernism remains widely influential within critical theory.

Key Figures and Contributions

Jean-François Lyotard and Questioning Meta-Narratives

Many key postmodern theorists are French intellectuals. At the forefront of these is the philosopher and literary critic Jean-François Lyotard, who was born in Versailles and had an international academic career teaching in Algeria and Paris as well as the USA, Canada and Brazil. A strong proponent of postmodernism, Lyotard was especially critical of the meta-narratives that held cultural positions of privilege in going largely unquestioned.

Lyotard was resistant to all general truth assertions and the meta-narratives of the Enlightenment that persisted through modernity. A meta-narrative, in his formulation, was any such story that serves as a cultural touchstone or organizing belief. Meta-narratives are particularly influential as foundational tales, such as the stories told about the pursuit of greater freedom and self-determinism in the American Revolution. These narratives are seen as establishing common values and providing a common cause in the completion of the narrative, as in the progression towards greater freedom through geographic conquest and social reform. Lyotard advocated for a position of general scepticism towards all such meta-narratives, and the ways in which they generalize histories and peoples. He described postmodernism as principally characterized by a sense of incredulity towards meta-narratives.

Michel Foucault and Critiquing Power

The philosopher and historian Michel Foucault also had an international career. He was born into an upper-middle-class family in France and worked as a cultural diplomat before pursuing a fuller academic career and teaching in France, Tunisia and the USA. Although Foucault did not describe his work as postmodern, his attention to the social uses of power has been widely influential and places him securely within postmodernist concerns of identities, the places of the marginalized and the critique of social structures and norms.

Foucault worked the archive and looked for otherwise neglected disruptions in history. He concerned himself with the ways in which social power operated and the effects it had in determining what kinds

of people, beliefs, dispositions and behaviours were marginalized and what kinds were normalized. Each categorization depended upon the other in its definition, Foucault argued, as the normalized is determined in contrast to the marginalized. The populations that Foucault focused upon included those labelled mentally insane, criminal and sexually deviant. In a typical example of his social analysis, Foucault adopted Jeremy Bentham's architecture of the panopticon, used for prison inmate observation and control, and adapted it to describe the general population's position in a surveillance society, thereby placing everybody within the panopticon.

Jacques Derrida and Deconstructing Texts

The philosopher and language theorist Jacques Derrida was born in Algeria. He is chiefly known for his theory and practice of deconstructionism, in which he takes apart a text to demonstrate the slipperiness of meaning between the text and what it is meant to represent. In this, Derrida shows how all statements include within themselves their own negation or deconstruction.

A key term for Derrida was *différance*, which he coined to play on the double meaning in French, both 'to differ' and 'to defer'. Derrida used the term to comment upon the inherently unstable meaning structures of language. The term refers to the reliance of language on creating meaning through the difference and deferral of what words do not mean, an always imprecise communicability based upon difference. These features of language presented for Derrida opportunities for the deconstruction of texts in order to showcase the constructed nature of meaning. Because Derrida saw all meaning as created through language—he claimed the world as a text—these principles of deconstruction were applicable well beyond the literary sites where Derrida practised them, with significant political and social implications to which Derrida turned his attention later in life.

Central Issues

Identity

Conceptions of identity and identity formation are a vital concern of postmodernism. For postmodernists, identity is fractured, heterogeneous, plural and largely socially determined. These theories of identity are in direct contrast to previous conceptions of identity as stable and continuous throughout a person's life.

To argue that an identity is fractured and plural is to contend that individuals are composed of a multitude of socially available identity positions, some more easily assumed or not assumed than others. In this way, identity is also socially constructed as it depends upon

the identity positions available and how those may be read by others. Postmodernists tend to talk about the 'subject' rather than the autonomous self in order to highlight the socially constructed nature of identity. This move away from the autonomous self corresponds in postmodern literary theory to the critic Roland Barthes's argument about the death of the author, an understanding that meaning was created not so much by authorial intent as by the work of readers and a work's context. Postmodernists also tend to reference identity in the plural; 'identity' then becomes 'identities' in order to recognize that an individual is always a composite contending with multiple identity positions.

The plurality of identities and their social nature within postmodern theory contributed to the rise of identity politics. While postmodernists held strong anti-essentialist positions and believed that there were no common qualities shared by any given population, they also held that the social positioning of different identities created distinct political interests for different identity groups, especially the historically marginalized and oppressed, such as women, ethnic and religious minorities, the poor and people of non-heterosexual orientations. While the rise of identity politics has helped some groups gain political standing and representation of their interests, those political movements have been criticized for coming at the cost of larger political solidarity and greater influence across marginalized and oppressed groups.

Truth

The critique of autonomous identities corresponds to postmodernism's larger concern with the nature of truth and the creation of meaning. While modernism upheld the importance of an individual pursuit of truth and meaning, postmodernism holds that there is no absolute and attainable truth. This position is in contrast to the progressive tradition of moving towards a greater truth and understanding, however imperfect or removed. Postmodernists instead focus on the socially constructed and determined nature of truth, placing postmodernists more securely within a relativistic perspective.

Reality and truth, for postmodernists, are functions of social agreements. They are constructed through language and other social conventions as reality is replaced by representations. Images, likenesses and references—which circulate without absolute foundations—become the primary substances of meaning. An increased reliance upon the media and technology, and the blurring of the boundaries between reality and virtual reality, bolstered postmodernists' claims that

reality is all a social agreement played out in a field of mirrors. Postmodernists did not argue that representations were without significance or consequence but rather that such representations and conventions were in fact the very sites of significance, and so they focused their critical attentions there.

These moves away from attainable and absolute truths coincided with the collapse of meta-narratives, the understanding of the world as a text and the desire to critique dominant and oppressive structures of power by revealing their artificiality. This was all meant to be liberating. In practice, however, some critics found the relativistic orientations of postmodernism to be inhibiting as it could be complicit with capitalism and provided no consistent or coherent values or positions upon which to ground moves towards greater liberation.

Media

The positions of postmodernism were exemplified by dramatic changes in the media. This is most evident in transitions to a more fractured and individual media experience and the dissolution of traditional broadcast boundaries of all kinds.

The postmodern era saw a shift from a few dominant television networks with codified broadcast schedules to a cable television—and later an Internet—era in which viewers could choose from a multitude of channels, watch as much or as little as they like and tune in on their own schedules. The viewing experience became more fractured and plural. It was constructed of individual media bits outside of the more consistent and progressive viewing experiences that networks had previously offered. Viewers became more active agents in their own viewing practices, and those practices were less homogeneous than before. In this fractured state, the media also made greater contributions to identity formation by being the primary site through which individuals were introduced to various identity positions and participated in their social construction.

The boundaries blurred by the media include the geographic and the cultural. Cable and satellite television, and later and more significantly the Internet, placed the world within easier communicative reach, even though that reach was limited to those with the necessary technological resources. This greater reach further exposed people to different cultures and beliefs, providing more significant opportunities for a relativistic questioning of the established ways of doing things and of dominant and otherwise unexamined meta-narratives. Furthermore, within national boundaries, the divisions between high and low cultures were troubled; television tended to flatten cultural preferences as

people watched the same shows. High culture was then brought down to the level of common culture through mass appeal, and the so-called low culture was elevated to the level of art through postmodernism's insistence that there is no objective standard by which to judge one cultural product or show it as inherently superior to another.

Continued Relevance to Action Research

Postmodernism's greatest relevance to action research lies in conceptions of identity and the critique of dominant power systems for their oppression of marginalized peoples. In focusing upon the fractured, plural and socially determined nature of identity, postmodernism fundamentally altered views of the self, although common ideas of an autonomous and consistent self persist. Identities are now seen as much more fluid and as operating within social situations and constraints in ways action researchers should continue to consider.

Similarly, critiques of power structures and their control of marginalized people, as best exemplified in the critical work of Foucault, offer a compelling conception of the relationship between the marginalized and the dominant within social systems. More than that, Foucault's work provides a strong critique of those systems, even as he demonstrates how the marginalized and the dominant rely upon one another to distinguish themselves, much as Derrida noted how textual meaning relies upon *différance*. An awareness of the functioning of these systems can provide both opportunities and motivation for the work of action research.

PRACTICAL KNOWING

Philosophers over the centuries have explored different forms of knowing, such as aesthetic, mystical, religious, interpersonal, moral and common-sense knowing. In action research, this is known as the extended epistemology. While action research belongs primarily to the world of practical knowing, which seeks to shape the quality of moment-to-moment action, it also draws on other forms of knowing. This entry describes the characteristics of practical knowing as it applies to action research.

The realm of practical knowing (sometimes called common-sense knowing) is directed towards the practicalities of human living and the successful performance of daily tasks and discovering immediate solutions that work. One of its particular characteristics is that it varies from situation to situation and from place to place. What is familiar and what works in one setting or place may be unfamiliar and not work in another. Therefore, practical knowing needs to be differentiated for each specific situation so that decisions about what to say or do are appropriate. Accordingly, practical knowing is always incomplete and can only be completed by attending to figuring out what is needed in situations in which one is at a given time. Accordingly, as no two situations are identical, practical knowing requires attentiveness to and inquiry in the present tense so as to learn what is needed for the task at hand and in order to move from one setting to another, grasping what modifications are needed, and to decide how to act.

Cycles of Action and Reflection

In working within the realm of practical knowing where knowing is always incomplete and where reflexive attentiveness to unfolding contextual dynamics in the present tense is central to both understanding and action, action research's emphasis on cycles of action and reflection is paramount. Action research builds on the past and takes place in the present with a view to shaping the future. Accordingly, engagement in the cycles of action and reflection performs both a practical and a philosophical function in its attentiveness and reflexivity to what is going on at any given moment and how that attentiveness opens up inquiry and decision-making and yields purposeful action.

Scientific and Practical Knowing

A contrast of scientific and practical knowing points to differences in how practical knowing has a concern for the practical and the particular, while science has theoretical aspirations and seeks to make universal abstract statements. Practical knowing is content with only what it needs for the task at hand, while scientific knowing tries to be exhaustive and seeks to know everything and state all it knows accurately and completely. Practical knowing is typically spontaneous, while science is methodical and develops technical jargon. Practical knowing is particular, contextual and practical, and it draws on resources of language with a range of meanings, body language, eloquence, pauses, questions, omissions and so on. In summary, practical knowing remains in the world of things related to us, while scientific knowing relates things to each other.

Scientific and Practical Knowing in the Academy

Practical knowing has been neglected by scholars. After the seventeenth century, philosophers turned to problems of the objectivity of knowing—a shift from knowing in a descriptive mode to knowing in explanatory mode, where things were no longer presented in relation to the knowing subject but were related to one another in recurring patterns. A tendency to relate any method of thinking to the subject was criticized as being subjective and invalid and limited to surface appearances, as contrasted with scientific patterns of knowing. In a parallel vein, the gap between theory and action widened as theory was developed apart from the action that underpins it and action developed without grounding in theory.

Action research constitutes a kind of science that works from a different epistemology that produces a different kind of knowledge, a knowledge that is contingent on the particular situation and which develops the capacity of people to address their own issues and solve their own problems. In using the term *scientific*, it is argued, there is a need to move away from adopting frameworks from the natural sciences in order to engage with the world of practice. Hence, action research places an emphasis on articulating a kind of scientific inquiry that is conducted in everyday life as a science of practice. This emphasis extends the normal connotations associated with the term *science* and grounds its use as an appropriate term to use in the realm of practical knowing.

PRACTICE DEVELOPMENT

Practice development is a facilitated approach to the development of person-centred and evidence-informed practice cultures in health care. It draws upon a variety of methods and approaches that together enable authentic engagement with individuals and teams to blend empirical evidence with the important personal qualities of professional practitioners, such as creative imagination, practice expertise and practice wisdom. The focus is on helping practitioners engage in active forms of learning (e.g. through play, creative problem-solving and/or observations of practice and storytelling) to bring about transformations of individual and team practices in the way health care is delivered. This learning and transformation that occur at individual and team levels are sustained by embedding both processes and outcomes in corporate strategy.

Practice development, whilst strongly connected with action research, has a slightly different emphasis or purpose. Whilst action research and practice development share the common purpose of bringing about changes in practice through collaborative and participative change processes, action research has an additional explicit additional purpose, that of generating new knowledge through the research process. This is not the case with practice development, where generating new knowledge is a secondary intent behind that of learning about the effectiveness of the change processes applied by practitioners in their everyday practice. For some practitioners, acquiring this new learning and internalizing it in a way that enables them to transform their own practice and that of others is

enough, whilst for others, they may apply systematic processes of evaluation to these active learning processes and, of course, therefore generate new knowledge that can be applied in a variety of contexts. It is this latter approach that brings practice development into the realm of action research and aligns it as a research process in itself.

Whilst there has always been informal practice development—meaning, individual practitioners changing their own practice and encouraging others to do so also—in the seventies, practice development became more formalized as a change process. Since its origins in the late seventies, practice development has been aware of the pitfalls of top-down change alone, and so it pays attention to these local practices in clinical settings whilst at the same time focusing on the need for a systems-wide focus on person-centredness and the development of person-centred cultures. In particular, practice development pays attention to what are increasingly acknowledged as ‘the human factors’ in health care—factors that acknowledge the importance of the connections between the desire for evidence-informed and person-centred practices and the need for practice cultures that are respectful of all people. Therefore, practice development pays particular attention to staff well-being, leadership, team relationships and morale in order to create a greater sense of belonging among teams, which in turn leads to greater clinical effectiveness and better patient outcomes.

The Evolution of Practice Development as Methodology

For more than 30 years, *practice development* has been used as a term to describe a variety of methods for developing health-care practice. In particular, the term has been used in the context of nursing development. In the early days of practice development, the term was used widely but inconsistently in British nursing. It was used to address a broad range of educational, research and audit activities. Practice development was underdeveloped as a methodology, and whilst there was a lot of enthusiasm for the methods because they resonated with the increased emphasis on quality improvement, clinical audit and using research in practice, there was no co-ordinated approach and, indeed, no common understanding of the most effective methodologies. Over the past 10 years, significant conceptual, theoretical and methodological advances have been made in the development of frameworks to guide practice development activities. Of most significance has been our increased understanding of the key concepts underpinning practice development work irrespective of the methodological perspective being adopted—for example, workplace culture, person-centredness, practice context, evidence,

evidence implementation, values and approaches to learning for sustainable practice.

The early proponents of practice development relied on what was then known about change management models and frameworks and adapted these in the context of bringing about systematic change to particular aspects of practice, such as medicine administration and other particular treatments and care activities for patients. The focus was not on changing the culture of practice settings to enable effective practice but, instead, on individual effectiveness and doing practices in ways that were technically competent and patient centred. Evaluating outcomes from these change processes, such as medicine error rates, fall rates and pressure damage incidences, was the key focus. So this kind of practice development can be considered as being *technical* in nature.

Further developments in practice development articulated the interconnected and synergistic relationships between the facilitation strategies used and the embedding of systematic, rigorous and continuous processes of change in order to achieve the ultimate purpose of evidence-informed, person-centred care as well as the development of knowledge and skills. The bringing together of these elements of change, empowerment strategies and individual and team learning shifted the focus on what practice development was about and led to a new understanding of practice development as being about emancipation from the taken-for-granted assumptions underpinning everyday practice. This approach to practice development was informed by the theoretical perspectives of philosophers such as Jürgen Habermas, Brian Fay and Paulo Freire, as well as action researchers such as Stephen Kemmis, Wilfred Carr and Susan Grundy. *Emancipatory practice development* explicitly uses critical social science concepts on the basis that the emphasis on the development of individual practitioners, their cultures and the contexts within which they work will result in sustainable change. Whilst one of the key distinctions between action research and emancipatory practice development has been the explicit intent of developing transferable knowledge in action research, this methodology of practice development articulates transferable principles for action and thus demonstrates a synergistic relationship between emancipatory practice development and action research.

More recently, new developments in practice development methodology through collaborative inquiry by an international community of practice developers, called ‘The International Practice Development Collaborative’, has pushed the boundaries of practice development even further and developed what is now known as *transformational practice development*. Whilst this kind of practice development has the same

shared purposes and underpinning values as emancipatory practice development, it has a particular focus on how we help human beings to flourish as individuals. The work of the author of this chapter along with that of Angie Titchen in particular led to the publication in 2008 of a new paradigmatic synthesis called ‘critical creativity’, which blended principles derived from critical science with those of creativity (where creativity is focused on accessing the inner knowing of individuals and drawing on a variety of sources of knowledge and expertise to create new understandings about the being and doing of practice). The intent of the critical paradigm with its focus on achieving democracy, inclusiveness and social justice is added to in transformational practice development, with its focus on human flourishing as the ultimate desired outcome. Earlier, it was suggested that the aim of practice development is the achievement of evidence-informed and person-centred practice. In this context, person-centredness means an approach to practice that is concerned with the quality of the relationships between and among staff teams and between staff teams and patients and families. Being person centred is linked to beliefs and values about the intrinsic moral good of personhood, with a focus on the uniqueness of the human individual, a concern with the meaning and purpose of human life and the promotion of an individual’s freedom to choose.

Facilitators of transformational practice development are, therefore, concerned with facilitating human potential and the growth of the whole person. This means finding out what people’s whole-being needs are, from their own perspective. By seeking an understanding of people’s perspectives about their own experiences, facilitators can help them focus on their unique experiential journeys of learning, critique, creativity and transformation. Within transformational practice development informed by critical creativity, therefore, there is a blending of the critical paradigm with its focus on improvement and transformation within the social world with that of attaining improvement and transformation of the individual lifeworlds of persons.

Practice Development Methods

It is clear that as practice development methodology has evolved and matured there is greater consistency among the methods used, set within a shared understanding of different methodologies. It is now generally accepted that when referring to practice development, emphasis is placed on

- improving patient care;
- transforming the contexts and cultures in which patient care takes place;

- employing a systematic approach to effecting changes in practice;
- employing systematic and creative approaches to active learning;
- engaging with a variety of forms of evidence and intelligences;
- employing practice development as a continuous activity normalized within teams;
- facilitating approaches that are enabling and transformational;
- using evaluation methods that are integrated with development processes and that are inclusive, participatory and collaborative; and
- identifying outcomes that demonstrate transferrable principles and key learning.

As the methodology of practice development has evolved, so too have the methods used for engaging with emancipatory and transformational processes. Processes such as developing shared values among team members, having a shared vision for ideal practice, developing team relationships, using work-based reflective learning strategies, engaging in critical questioning and adopting a systematic approach to changing everyday practice have been developed into facilitation strategies that set out to help individuals become empowered with the knowledge, skills and expertise to develop practice. There is shared agreement among practice developers that the following methods are the most effective in bringing about emancipatory change:

- Working with ethical processes that emphasize collaboration, inclusion and participation
- Analyzing stakeholder roles and ways of engaging stakeholders
- Focusing on being person centred and both process (way of working) and outcome (creating person-centred cultures) oriented
- Establishing and working with shared values as the ‘benchmark’ for practice
- Developing a shared vision for the future of practice
- Developing and maintaining collaborative working relationships
- Using creative, reflective and active learning strategies that generate a culture of high challenge with high support
- Establishing an evaluation framework that is integrated with the development work; is collaborative, inclusive and participative and which pays attention to the effectiveness of development processes in the context of the outcomes achieved
- Rewarding success through celebration, recognition and acknowledgement

In addition to these methods, transformational practice development places emphasis on the following:

- Blending and weaving different art forms with reflective and cognitive processes
- Creating the conditions for creative imagination to flourish
- Connecting with nature and the natural environment as a stimulus for engaging different intelligences (e.g. emotional intelligence and spiritual intelligence).

These methods are collectively focused on developing evidence-informed and person-centred cultures so that the care that patients experience is of the highest quality possible and the places within which health-care workers deliver care practices are enabling, facilitating and rewarding and ultimately enable human flourishing.

Practice Development and Action Research

As the methodology of practice development has evolved, the connection between systematic approaches and action research has become clearer. The origins of practice development lie in a commitment to enabling practitioners to change their practice through equipping them with the skills and knowledge to critically reflect on their practice and identify ways of developing it. This emphasis was different from that of action research, as the focus was not on the answering of particular research questions through the taking of action and its evaluation. Whilst the development of transferable knowledge is the primary purpose of Participatory Action Research, this has been a secondary purpose of practice development. However, as the methodology has evolved, this distinction has become more blurred, and in a recent publication by the Department of Health, Social Services and Public Safety in Northern Ireland, a distinction was made between practice development with a 'small *d*' (with its focus on helping practitioners to change their practice and the culture of practice in order for it to become more evidence informed and person centred) and practice development with a 'large *D*' (with its focus on the systematic development of workplace cultures towards settings that would facilitate better person-centred practice and the generation of new knowledge through the evaluation of processes and outcomes). The latter kind of practice development aligns itself within the same philosophical and methodological perspectives as those of participatory, emancipatory and transformational action research. It uses approaches to learning in and from practice as a key strategy for transforming practice. Skilled facilitation and formal systems for enabling learning as well as its assessment, implementation and evaluation in

the workplace are instrumental to effective practice development. Generating new knowledge through the systematic development and evaluation of the practice development activity and that has the potential to be transferrable is as important as the development programme itself. Methodological principles of collaboration, inclusion and participation are critical to the design of the programmes, their facilitation and their evaluation. New knowledge is therefore co-constructed through these principles. So whilst practice development has retained a distinct focus on helping individuals and teams to develop their practice, the evolution of the methodology has created greater alignment between the underpinning values of practice development and action research, and their potential to generate new potentially transferrable knowledge is shared.

PRACTITIONER INQUIRY

Practitioners are managers, teachers, nurses, engineers, doctors or anyone who gets the job done. Practitioners pride themselves on fixing problems, not just looking at or inquiring about things. Even so, practitioner inquiry need not be a contradiction in terms, and action research can help.

Skilled practitioners may well be practised at solving everyday problems that get in the way of getting the job done well. After many years, this becomes instinctual, which is effective, but it can become a problem if the old methods do not solve new problems. David Hume in his *Treatise of Human Nature* in 1739 said that we are creatures of habit, not reason. So even good practitioners need logical processes to help them overcome the limits of their own instinct and habit to do the same thing over and over. Even Sir Karl Popper recognized the inherent tendency of scientists to only seek information that confirms their own instincts. His version of scientific method (1972) was one way of helping scientists to challenge their own ingrained beliefs and instinct.

Popper's method works well with some problems, especially those that are within closed systems with relatively simple interactions between the component parts and little impact from outside influences. Practitioners, however, work in what Peter Checkland called in 1982 a 'human activity system'. They are open systems with complex relationships between the people and components in the systems and the wider environment.

Action research consists of methodologies that can help practitioners address real-world problems by learning by doing when their old methods are not suited to the new problems.

Action Research and Practitioner Problem-Solving Styles

The fundamental logic of action research is to have a clear intention, which leads to a clear plan, which when implemented can be checked against the original intention, and the plan can be reviewed for its effectiveness in achieving the intention. A new intention is the next issue for a dynamic human activity system to address.

The work of Peter Honey and Alan Mumford in 1982 on learning styles suggests that this might not be the case. Their four learning styles are also four different ways of addressing problems. *Theorists* like to look at the big picture and create a theory to explain the problem but might be less inclined to follow through with a plan. *Pragmatists* like the 'tried-and-true', which might not always work in new situations. *Reflectors* like to consider a situation from all angles but might be less interested in fixing it. Many practitioners are *activists* whose strength is to jump in to solve a problem. But if they do not take the time to understand the problem first, they might not solve the real problem.

Therefore, consciously and intentionally implementing a structured action research approach to problem-solving can enhance the natural problem-solving style of all practitioners, particularly activists who might 'jump to a solution' before identifying the problem.

Action Research for Practitioner Inquiry

One way to implement an action research approach to problem-solving is to systematically use action research at each of the stages of problem-solving:

- Defining the problem
- Planning and evaluating
- Considering what needs to happen next

Action Research for Defining the Problem

What Is a Problem?

The strength of an activist approach to solving practical problems is the ability to jump in and get started. However, jumping to a premature solution can cause unintended consequences and even make the problem worse. This can happen when practitioners do not appreciate the difference between a problem and a solution. A common mistake is to believe that a problem is the lack of something—money, support, direction, staff and so on. If the programme had more of these, all would be well. But this does not define what problem the additional resources would fix. A typical example is where more and more money is thrown at a problem and the problem remains or gets worse.

Jumping to a solution rather than defining the problem can result from a belief that the best way to work with complex problems, like human activity systems, is to break them down into their component parts and work with one component at a time. This is a reductionist approach and can work with simple, closed systems, like machines. This approach does not work so well in human activity systems, which are open systems. Ludwig von Bertalanffy described open and closed systems in his *Outline of General Systems Theory* in 1950. Open systems can be investigated more effectively by understanding the relationships between the components and the people within the system and by investigating the relationship of the whole system with its environment. Checkland, in his *Soft Systems Methodology*, describes human activity systems as relationship-maintaining systems rather than goal-attaining systems. So the dynamic of a human activity system is to use the positive and negative feedback loop to maintain the system in a steady, if undesirable, state.

An example of the difference between reductionism and systems theory can be seen in changes in family therapy. In the old, reductionist approach, family therapists consistently failed to 'improve' the identified 'problem child' whom families would present for therapy. No matter how much the individual improved, once he or she returned to his or her family, the behaviour quickly became problematic again. The internal pressures of a family that believed it had a 'problem

child’ came into play to re-establish the predictable but unhappy state of a ‘family with a problem child’. Further, if the ‘problem child’ is not returned to his or her family, another family member will become the ‘problem child’ in order to maintain the steady state of a ‘family with a problem child’. The systems approach to family therapy means that therapists now deal with problem families rather than problem children and work to improve the relationships between all the family members and the extended environment to create a different steady state of a ‘functioning family’.

Before family therapists or other practitioners can work to improve a situation, they need to have a good understanding of how it works in its current, if dysfunctional, steady state.

Define a Problem Situation

The rich-picture stage of Checkland’s soft system methodology is a tool that practitioners can use to understand the problem situation. Checkland’s stakeholder analysis can help practitioners identify a number of potential courses of action to improve a situation, rather than one right answer.

**Developing a Rich Picture:
Convergent Thinking**

A rich picture is a picture of the current situation that is inclusive of all the elements of the problem situation. It is ‘rich’ in detail. A human activity system is a relationship-maintaining system rather than a goal-seeking system; therefore, it is important to draw a picture of current relationships. This phase can be difficult because it is easy to become so overwhelmed with detail that it looks like chaos. Hence, people often avoid this uncomfortable stage by rushing to a premature decision. However, poor decisions are made when not enough options are canvassed at the beginning. Therefore, it is important to stay in the uncomfortable stage of convergent thinking long enough to fully describe the current situation, knowing that in the next phase divergent thinking will start to find patterns in the chaos that suggest options for action versus one right answer.

A rich picture is best drawn with minimum words to engage the big-picture thinking skills of the right side of the brain. The logic of the left side of the brain comes into play in the next analytic, convergent thinking phase.

Procedure

Using a very large chart or whiteboard, and with the input of as many relevant people as possible, draw the current situation, with minimal words. Record elements of the following:

- Slow-to-change *structures*—the organizational structure and environmental constraints (physical and social), physical layout, power hierarchy, espoused values, formal reporting structure and patterns of communication (formal and informal)
- Continuously changing *processes*—roles, relationships, activities, formal and informal communication patterns and values in practice
- The relationship between structures and processes, which is the *climate* or *culture* of the situation and is frequently where some of the core characteristics of the problem situation are perceived

Identifying Potential Courses of Action

The stakeholder analysis tool shown in Table 1 can enable a practitioner to identify several courses of action for improving a situation by, firstly, understanding who benefits from the current situation and, secondly, suggesting ways of maximizing the benefits for all people in the system. The benefit of identifying several courses of action is that if the first approach is not as effective as intended, there are other options to try.

Action Research for Planning and Evaluating

If practitioners are working on a whole new problem in a ‘greenfield’ problem situation, then they will need a planning tool. If the practitioners are addressing a current problem, then they are more likely to need an evaluation tool. However, a project can only be evaluated if it was planned with clear intentions and targets. Therefore, planning and evaluation are two sides of the same coin. Bob Dick’s Snyder Evaluation Process of 2006 can be used for both planning and evaluating a project.

<i>Stakeholders (By Name and by Role)</i>	<i>Their Stake (What’s in It for Them in Qualitative and Quantitative Terms?)</i>
<i>Actors:</i> The people or groups who carry out the activities of the system—that is, do the job	
<i>Customers:</i> The direct beneficiaries or victims of the situation	
<i>Owners:</i> The people or groups who have the power to support or abolish the system	

Table 1 Stakeholder Analysis

The elements of the Synder Evaluation Process, as shown in Table 2, are as follows:

- The vision or ideal for the programme—that is, the reason it exists and the main objectives of that vision
- Specific definable targets for each objective in order of priority
- Specific activities for achieving each target and statements on the intended impact of each activity on the target
- Both material and non-material resources that are allocated to all activities—that is, skills, time, goodwill and so on.

At the planning stage, it is important to ensure congruence across the plan—that is, that each objective has a target, each target has at least one activity, all activities are resourced, all resources are consumed only by the intended activities and all activities relate to at least one target.

At the evaluation stage, practitioners can develop a suite of performance indicators that link the resources used and the actual impacts directly back to the vision and its objectives.

Practitioners are now in a position to determine to what extent their programme has achieved its objectives and why this is the case—rather than assess it

against vague intentions and a measure of inputs. This is a form of evaluation that Michael Quinn Patton in 1980 called summative evaluation. However, Dick’s method of short-cycle evaluation, from 2006, as an optional part of the Snyder Evaluation Process, is what Patton calls formative evaluation and is a method for developing a self-improving system.

Action Research for Considering What Comes Next

The steps in Dick’s short-cycle evaluation are as follows:

- Identify the evaluation criteria (the most sensitive and readily available indicators)
- Identify the sources of that information
- Create information systems
- Review the continuing appropriateness, sensitivity and ease of operation of the information system

A simple but targeted information system can help practitioners quickly and effectively respond to problems as they arise.

Action Research for Practitioner Inquiry

Practitioners are problem-solvers. The systematic logic of action research fits naturally with practitioners’

<i>Vision: The Reason for the Project—Usually Too Broad to Be Evaluated Directly</i>	<i>Specific, Time-Bound Definable Targets for Each of the Main Objectives</i>	<i>Activities and Their Intended Effects</i>	<i>Resources: Tangible and Intangible—Money, Materials, Services, Information, Time, Goodwill, etc.</i>
Objective 1 (O1): More specific than the vision, in order of priority, but still not able to be evaluated directly	Target 1 (T1)—in order of priority	List activities based on their intended effects on O1 T1 (a) (b) etc.	Allocate resources against each activity
	Target 2 (T2)	List activities based on their intended effects on O1 T2 (a) (b) etc.	etc.
Objective 2	T1 T2	etc.	
Objective 3 (4 or 5 is enough)	T1 T2		

Table 2 Snyder Evaluation Process

instincts and can enhance these instincts with practical ways of collecting good information to better inform how they define and address a problem.

PRAGMATIC ACTION RESEARCH

Action research comes in a wide variety of forms, each having distinctive strategies and emphases. No single approach can stand in for the whole field because each has to be understood for what it proposes to accomplish and the strategies and mindset it enacts. Pragmatic Action Research focuses on the ongoing and purposive redesign of action research projects to enhance co-generative learning among the participants while they are engaged in the process. It also includes their collaborative evaluation of the results of their action designs and, if necessary, the redesign and redeployment of actions to better resolve the problems at the centre of the effort.

In using the term *co-generative research*, Pragmatic Action Researchers are referring to a form of action research collaboration in which the participants create an arena for learning within which all the stakeholders, including the facilitators, focus their learning efforts. Co-generative research is shared and ongoing. Going beyond an ethical respect for difference, Pragmatic Action Research welcomes differences as potential sources of experiences, ideas and strategies gained through the different life trajectories of the participants, upon which the collaborative group can build new solutions to shared problems.

Pragmatic Action Research Aims

Like all forms of action research, Pragmatic Action Research aims to produce liberating outcomes but without defining a priori or in absolute terms what should count as ‘liberating’. To a pragmatic action researcher, improving the ergonomics associated with the work of nurses in a hospital by engaging the nurses, doctors, patients and action research facilitator in co-generative dialogue can be just as ‘liberating’ when it improves the working life of nurses as can be the promotion of land reform for landless farmers in a society where the landless starve. Pragmatic Action Research views both scenarios as liberating—obviously in different ways—but insists that they can be similar in using collaboration among the stakeholders to move from a less acceptable to a more liberating and sustainable situation. In Pragmatic Action Research, the belief is that any particular human problem is worthy of attention if that problem negatively affects the quality of life of sincere people and creates obstacles to their flourishing as individuals and communities. Thus, Pragmatic Action Research sees the problems of people in industrialized societies to be as much a part of the mission of action research as the problems of the dispossessed and impoverished.

Pragmatic Action Research is by no means naive about power differentials and vested interests. However, Pragmatic Action Research believes that considerably more positive change is possible in coercive situations than many determinists think. An unequal society, an unfair political economy and vested interests by themselves do not prohibit significant improvements in the lives of individuals and communities through the construction of arenas for dialogue and learning. Gathering people to share their experiences, knowledge and aspirations under conditions in which the stakeholders feel both respected and safe has powerful effects on many apparently intractable problems. Following the line of argument of thinkers like Michel Foucault, Pragmatic Action Research sees power as something that can be generated from anywhere in a system. Power is not a finite source of control, monopolized by the few against the many. There are many more either win-win solutions or at least win–not lose scenarios possible under unequal conditions than the stakeholders often see at the beginning of the process.

Guidelines to Pragmatic Action Research

There are a few guidelines that pragmatic action researchers generally follow. They build arenas for co-generative learning without using their influence to predetermine what should be learned about and without allowing one stakeholder group to dominate others

in the problem definition phase. The role of the action researcher is to make the conversation fair and safe with the aim of 'keeping the conversation going', as Richard Rorty famously described pragmatic practices. Enabling people to speak to, hear from and learn from one another does not dissolve all problems, but it may permit sufficient mutual understanding to make certain intractable problems become more tractable.

The pragmatism of Pragmatic Action Research extends to methods as well. Pragmatic Action Research will use theory and methods from any corner of the sciences, social sciences and humanities if they offer some hope of helping a collaborating group move forward. If numbers are needed, statistical social science, surveys and other formal techniques can and will be used. If subtle cultural understandings are needed, then leading-edge feminist, hermeneutic, linguistic and other perspectives are used. If an estimate of the contamination of well water by an oil company is needed, then geologists and hydrologists are welcome partners. The mix and balance of these approaches is adjusted to the needs and priorities of the co-generative learning community.

Pragmatic action researchers work in a variety of ways. They often work in a plenary format, where everyone is able to hear from everyone else, but small groups and action teams often carry the bulk of the effort to sort out problems, gather evidence and build interpretations. Individuals also have the latitude to participate because sometimes they are uniquely situated to be of help. The guiding premise is that the group needs to know what its objectives are, what resources it has and what it needs and to mobilize them in whatever way seems manageable with the resources available. Once that information is widely shared, then working in smaller groups with occasional meetings of the whole group is a standard way of operating.

Examples of Pragmatic Action Research

An example of Pragmatic Action Research is an initiative by the Norwegian government to encourage older workers, particularly skilled workers, to continue working beyond the standard retirement age. This arose both because many older workers are in good health, live a long time after retirement and often struggle with being retired. Another reason is that they can continue contributing to the pension system longer rather than withdrawing resources from it. The social partners agreed to support work on this, and the action researcher, Anna Inga Hilsen, then engaged all the stakeholders in a process of dialogue, analysis and action planning that eventually came to focus on the need to reorganize and improve workplaces and work organization to make it reasonable for older workers to wish to continue to work. What needed to be done was

decided by the workers themselves and not imposed on them from above.

A project on composting (dry) toilets in Mexico City was developed by Ana Cordova, who combined an interest in environmental sustainability, hygienic improvements for residents of Mexico City with poor access to water and sewers and more general community development in poor areas of the city. Beginning with a strong technical design and tested models of these apparatuses, Cordova enlisted local community leaders, families willing to try these devices and a broader educational campaign in which this composting toilet initiative was part of a larger effort to develop a stronger civil society in poor urban areas.

In both cases, groups were formed, multiple stakeholders engaged and the local participants had a significant role in defining the agenda, in planning the changes, in redesigning the projects and ultimately in helping to carry them forward.

Historical Influences and Current Practitioners

This thread of action research derives heavily from key historical figures in philosophy. Among them are William James, John Dewey and Richard Rorty, whose development of American pragmatism is central to this practice. The driving force for this kind of approach is the belief that people placed in a situation to learn effectively together are able to design ways to build a better future and that these processes issue, in Dewey's words, 'warrants for action', meaning that the results are both desirable and believed to be sufficiently well understood as to be safely actionable. This testing of ideas through their efficacy in action is a hallmark of Pragmatic Action Research, though it also inheres generally in action research.

The hermeneutic philosopher Hans-Georg Gadamer is also a major inspiration for this approach. Gadamer brought new credibility to hermeneutics by showing how the collaborative processes of interpretation and reinterpretation can lead to a kind of workable consensus (never final) that is capable of permitting people to continue their interactions and development.

Pragmatic Action Research also draws inspiration from some of the work of the Frankfurt School, most particularly the work of Jürgen Habermas, and from linguistic philosophy as developed by Ludwig Wittgenstein and his followers, such as Björn Gustavsen.

Within action research itself, leading figures promoting this pragmatic approach include Fred and Merrelyn Emery, the inventors of the Search Conference and participants in key developments in Pragmatic Action Research at the Tavistock Institute and in Norway in collaboration with Einar Thorsrud.

Among current practitioners, we would count Gustavsen, Øyvind Pålshaugen and many of their colleagues at the Work Research Institute of Oslo, Norway, as well as Morten Levin and his group, who have engaged in major regional and organizational development projects in this approach and trained generations of doctoral students in action research.

Strategies and Practices of Pragmatic Action Research

Among the work strategies that typify this approach are Search Conferences and attempts to develop multi-sited projects capable of effecting social change on a larger scale through networking the co-generative learning arenas.

There are significant national differences in Pragmatic Action Research. In Norway and Finland, there is a degree of national support through agreements among the 'social partners' (employers, unions and government) to fund Pragmatic Action Research work on particular subjects of national interest. There were strong developments in Sweden as well, but the past decade of increasingly conservative politics in most places, including Scandinavia, have undermined much of this work.

By contrast, attempts to engage in Pragmatic Action Research in a place like the USA face radically different challenges. There are no 'social partners', and civil society activities are heavily constrained by the neo-liberal market ideologies that drive many policies and policy development processes. Thus, Pragmatic Action Research often starts in small segments of local institutions in the USA, achieves gains and then attempts to use the successes as ways of encouraging others to engage in such efforts.

Rarely is Pragmatic Action Research used to create an organization. Rather, it takes place within existing structures and organizations that find themselves needing to change but are stuck for reasons that they cannot seem to address on their own. When Pragmatic Action Research does create an organization, it is often an offshoot of a process of co-generative learning that has led a group of stakeholders to decide to create a special-purpose organization as part of their efforts to solve their problems.

Though it is pragmatic, Pragmatic Action Research is not easy. Most problems facing organizations or groups that are stuck are quite complex and multidimensional. Quite probably the complexity of most situations exceeds the knowledge capacities of even the best-trained action research facilitators. As a result, such people must be simultaneously confident enough to keep the process moving but humble enough to be honest about what they don't know and about the need

to bring in others with the expertise the group have identified as necessary to solve their problems.

Training such facilitators is a serious challenge because most academic institutions are filled with Tayloristic bunkers of disciplinary expertise, which actively inhibit the kind of flexible multidisciplinary and humility needed to conduct this work properly. Thus, pragmatic action researchers must be trained against the grain of most institutions of higher education.

All Pragmatic Action Research processes have a strong communication and education component. Pragmatic Action Research is about creating co-generative learning arenas and also about helping stakeholder groups develop the capacity to create and manage such groups on their own so that this kind of problem-solving can continue without such dependency on outsiders.

Pragmatic Action Research does rest on a slippery ethical or political slope. By turning away from radical idealism and radical solutions, Pragmatic Action Research tries to find spaces for liberating action within existing structures and groups. In doing this, there is always a risk that Pragmatic Action Research will settle for less change than is needed and will be so non-confrontational as to leave too many unfair power relations intact. There is no clear guideline on how to avoid this kind of co-optation, and the risk is real. However, pragmatic action researchers think that the risk is worth taking.

PRAGMATISM

Pragmatism is a distinctly American philosophy that aims to uncover practical knowledge—knowledge that *works* in a particular situation. The acquired knowledge is evaluated by reference to its problem-solving capacity in everyday life rather than its universal applicability, which makes pragmatism a fruitful tool for action researchers.

Pragmatism is better described as a philosophical method for doing rather than a philosophical theory per se. It is not simply a collection of viewpoints about a specific concept, such as truth, identity or reality. Pragmatism concerns how humans should conduct business, as managers, accountants or researchers, whenever engaging in any form of inquiry. In its narrow interpretation, pragmatism is a method of determining the meaning of concepts to show that there is no meaning without practical consequences. All concepts are therefore contextual by nature and have different meanings for different people in different situations. The meaningfulness of knowledge is determined by its ability to solve a practical problem.

As a result, knowledge is seen as a contextual property that evolves through everyday practices and is measured by its practical consequences. Hence, the notion *practical knowledge* is more appropriate in pragmatism as it reflects the situational creation of knowledge with regard to its problem-solving ability. In the same vein, action researchers view the development of knowledge as part of the daily inquiry process rather than as a monopolistic notion of academics or social scientists.

On a broader level, pragmatism is a method for uncovering contextual truth. For pragmatists, truth is naturally contextual since our knowledge and beliefs about scientific concepts, on which humans base their understanding of the world, are only *true* as long they bear practical consequences. Truth is provisional; it is the result of ongoing practical inquiry in the form of applying practical knowledge in different situations. Truth is defined by its pragmatic use in ongoing experiences and not in association with the objective qualities of the concept. Truth is the result and goal of inquiry, something that many action researchers would agree with. Inquiry is the reflective and iterative process of solving a particular problem. Throughout the process, consensus about both means and ends has to be established, which results in the co-ordination of thought, knowledge and action.

Origins of Pragmatism

The origins of pragmatism can be traced to the year 1870. A group of young students from Cambridge, Massachusetts, including Charles Sanders Peirce and William James, founded the so-called Metaphysical Club. The young men met regularly to discuss their views on modern philosophy and its associated problems, with the distinct viewpoint that there is no knowledge apart from the knower, opposing the predominant notion of objective and absolute truth at the time. Peirce and James used the debates to become the pioneers of pragmatism. Not long after these informal meetings, a more comprehensive description of pragmatism emerged, beginning with Peirce’s two essays ‘The Fixation of Belief’ (1877) and ‘How to Make Our Ideas Clear’ (1877). Shortly after, in 1878, James published a series of articles himself, in which he manifested his philosophical take on pragmatism.

The well-travelled James inspired and derived inspiration from a diverse assortment of fellow travellers, sympathizers and acute critics. As a result, pragmatism gained prominence and support and was soon closely followed by intellectuals in and outside America, including John Dewey, George Herbert Mead, Giovanni Papini, Alfred North Whitehead and F. C. S. Schiller. A multiplicity of forms of pragmatism

emerged, but the works of Dewey and Mead, from the Chicago School, are particularly recognized as important texts. While Dewey, deeply influenced by James, became a prominent figure in applying pragmatism to the social sciences, Mead became one of the founders of social psychology and the symbolic interaction movement.

More recently, Richard Rorty had a significant impact on the pragmatic community by introducing linguistic pragmatism. In his work, also described as neo-pragmatism, Richard Rorty integrated and applied the principles of Dewey, Georg Wilhelm Friedrich Hegel and Charles Darwin and questioned the traditional concept of knowledge as a mental mirroring of our external world. Rorty's linguistic pragmatism highlighted the importance of conversations in the process of inquiry, which allow us to *use* our reality to get what we want. As in the first pragmatic wave, many figures have significantly contributed to the neo-pragmatic movement, such as Hilary Putnam and Susan Haack.

Since its origin in the late nineteenth century, the pragmatic method has been applied to many professions. Hence, it accommodates a number of theoretical viewpoints, some of which are conflicting. The internal disagreement makes it difficult to single out one precise form of pragmatism. Nonetheless, the main principles remain; pragmatism is a problem-solving method that aims to create practical knowledge through (scientific) inquiry.

Conceptual Overview

Pragmatism emerged as a critical response to Western philosophy and its existing dualisms. Dualism refers to a division between mind and body, proposed by the French philosopher René Descartes, who believed that knowledge exists independently of the knower. Pragmatists have no interest in dualistic debates around philosophical concepts, such as positivism versus postmodernism or theory versus practice, as they are perceived as mere language games. The debates occur independently of the context they are in. Instead, pragmatists are concerned with the application, integration and meaning of these philosophical concepts in daily life, rather than dealing with their objective meaning. Pragmatism rejects the notion of objective truth since all knowledge, belief and scientific concepts are provisional. Knowledge is contextual; there is no knowledge apart from the knower, and truth only exists as long as a concept offers meaningful practical solutions.

As a result of the discussions around traditional philosophy, pragmatism is a method that connects dualisms by focusing on the inquiry process that is set out

to solve problems. Pragmatism is built on two inter-related conceptualizations of philosophical inquiry: (1) interpretation of meaning and (2) interpretation of truth.

Interpretation of Meaning

In a narrow sense, pragmatism is merely an *interpretation of meaning*. The pragmatic maxim is mainly concerned with solving problems. Problem-solving as such incorporates the successful application of concepts, beliefs or theories in a particular situation. The main measure of success is a satisfactory outcome with regard to the problem to be addressed. Satisfaction, however, is a state of mind that occurs in the present moment and creates a logical problem as the present tense fails to provide meaning. Meaning can only be established through reflective experience.

At its core, experience enables the verification process of truth as it allows us to retrospectively attribute meaning to our actions. The significance of experience, however, transcends much further: It is the starting point when a problem is encountered, the source for potential solutions as well as the outcome of the tested solutions. In other words, the pragmatic concept of experience is threefold: Firstly, it is the product of the interplay between objects and action; secondly, it enables the creation of practical knowledge by engaging in problem-solving activities and, thirdly, it serves as a point of reference for verifying the meaningfulness of an act. As a result, pragmatists consider experience as plural, equivocal and in constant flux. Problem-solving becomes a process in which meaningfulness is created through the deliberate application of past experience, while new experiences are accumulated simultaneously. These meaningful activities lead to integration between the problem and the actor, the subject and the object, respectively, which allows pragmatism to reject existing dualisms. This view of meaning is mainly associated with James and Dewey.

For Peirce, on the contrary, the meaning of any concept is merely the sum of its perceivable practical consequences. Peirce introduced this notion of meaning in his work *Fixation of Belief* (1877), in which he argued that the meaning of a word must be understood with regard to the habits associated with it. In the same way, meaning is established for any concept, belief, idea or anything that acts as a sign. Peirce's interpretation leads to two conclusions: First, concepts without any perceivable practical consequences are meaningless, and second, if multiple concepts have the same practical consequences, the concepts are identical.

While Peirce's maxim deals mainly with the meaning of concepts, it is often perceived as his notion of

pragmatic truth. However, it is in fact just an application of the criterion of meaning to the concept of truth. Peirce defines truth as the state of a belief that ultimately has to be agreed upon by all who investigate, making truth independent of the individual. Peirce's truth is therefore closer to the natural sciences than that of James, Dewey or Schiller. Influenced by his scientific background, Peirce's truth is ultimately achieved through endless *abductive inference*. Abduction, as opposed to induction or deduction, is a form of inquiry that starts with a problem and then iteratively rejects or verifies the varieties of possible explanations before arriving at the best explanation, which allows the *fixation of a belief*. To other pragmatists, Peirce's proximity to the natural sciences increased the distinction. To avoid criticism, Peirce later renamed his doctrine *pragmaticism*. A major point of critique is the perception that pragmatism is more than a philosophy of meaning; it is a philosophy of truth.

Interpretation of Truth

In a broad sense, pragmatism is an *interpretation of truth* that disregards the traditional notion of objective truth entirely. Many pragmatists promote an instrumental version of truth, in which *true is what works*, implying that something is true as long as it is advantageous to believe so. For James, truth is made in the course of human experiences and cannot be separated from the context or the human actor. Any form of knowledge, a belief or a scientific concept *becomes* true through its successful application in a particular context. Two entwined aspects must be highlighted with regard to the pragmatic notion of truth: (1) truth is provisional and (2) truth results in practical consequences.

First, for pragmatists, there is no single absolute truth; there are multiple truths out there, all of which are context dependent. Truth is only provisional and therefore always subject to fallibility through further human inquiries. In other words, something is true as long as it provides a satisfactory practical consequence. Truth is simply the currently best knowledge available for a particular purpose. Hence, it is legitimate to believe in these provisional truths. A true believer is, however, constantly tested in everyday life through the human process of pragmatic inquiry. The aim of the process of inquiry is not to produce a final and objective truth. The process of inquiry verifies or rejects the problem-solving ability of a particular truth in a certain context. Nevertheless, a particular belief does not become truer even though it has been verified numerous times, since pragmatism rejects an absolute notion of truth. Despite an exceptionally high number of verifications, there may still be situations in which the belief fails to provide a satisfactory outcome.

Secondly, pragmatic truth must be investigated in correspondence to practical consequences—precisely, the satisfactory outcome of a meaningful action. For James, truth is the ability of an action—undertaken in correspondence to existing beliefs—to provide satisfactory consequences and is thus concerned with the relations of certain past experiences to new experiences. In a practical sense, the relation of action to satisfactory outcomes is to be seen as the achievement of a purpose through intentional practice. Truth can therefore occur on an individual level through personal experiences and is not the property of an objective outside world; truth is not limited to time, persons or circumstances. Accepting truth on an individual level implies a certain level of subjectivity, which allows non-experimentally testable concepts to be claimed as true.

In this interpretation of pragmatic truth, scientific theories, beliefs or ideas become instruments to *make* things true. For James, something is true as long as it helps the inquirer to get satisfactory results in relation to other parts of our experience. In that sense, facts, whether in the form of the theories, ideas or scientific concepts, are not true per se; they are only true when one experiences their practical consequences in particular situations.

The pragmatic concepts of truth and experience are deeply entwined. In fact, truth is considered as part of our ongoing experience. In that sense, action research must not only be informed by scientific theories, it must also include practical experiences in the form of testing and be verified by practical hands-on experiences that enable future actions to take place in meaningful ways. Whilst the process of pragmatic inquiry is experimental by nature—since every situation is inherently different—meaningful experiences provide comfort and guidance for future acts.

Critical Comments

Pragmatism is a multifaceted philosophy that has been applied and conceptualized in many different ways and professions. It is a doctrine whose supporters have always been engaged in critical internal debates: for instance, Peirce and James, whose disagreement about the fundamental assumptions of pragmatism led Peirce to rename his version of pragmatism as *pragmaticism*, or the more contemporary debate between Rorty and Haack, which shows that the pragmatic philosophy is still vibrant and alive. While this internal disagreement enabled the field to flourish and grow, the conflict is also a growing ground for criticisms, especially from those who strive for certainty.

Critics argue that pragmatism lacks explicitness and rigour as it does not aim to uncover certainty. Pragmatism therefore cannot be seen as a process of scientific

inquiry, making it relativistic in its core. The main concern is this: If there is no way of finding absolute truth or certainty, how can we know that something is better than another? Certainty as a philosophical concept is not addressed in pragmatic philosophy, as we can never know whether something is absolute. Pragmatism as a non-dualist philosophy rejects the object/subject categorization, which is a precondition for certainty—something that is, however, promoted by dualist philosophies, such as positivism. Pragmatists believe that object and subject cannot be separated and are therefore intersubjectively connected. More precisely, *intersubjectivity* describes the state in which subjects and objects affect and shape each other in everyday practice. It erases the subject/object division, which makes it impossible to uncover objective or absolute certainty, or truth.

The pragmatists address the issue of certainty by systematically bridging theories and experience. Truth is merely determined by the problem-solving ability of theories or any other form of knowledge. Theories are merely tools that become true through successfully solving a particular problematic situation. This process is inherently rigorous, as theories or scientific knowledge is often formulated in a precise and structured way. One can never know for certain whether a specific theory solves a certain problem—even though it has been verified multiple times. Theories are therefore constantly tested, verified and falsified by a practical community of inquiry. This verification process then leads to experiences, and subsequently to formalized knowledge.

Pragmatic Knowledge

The pragmatic concept of knowledge, and the way it is acquired and explained, is attractive for action researchers. Mainly promoted by Dewey, pragmatism opposes the view that knowledge exists independent of the knower, reducing the role of the knower to that of a mere observer. For the pragmatist, knowledge acquisition is subject to the occurrence of an actual problem that demands a concrete response, and thus the active participation of an actor in a problem-solving process. *Indeterminate situations*—the term that Dewey uses to describe a problem—are the conditions that result in inquiry. Knowledge acquisition is the process of successfully solving an intermediate situation, which involves reorganizing, verifying and testing multiple resolutions. Knowledge is therefore necessarily experimental, and it is only reflection on a successful problem-solving act that results in meaningful knowledge, which implies that there is no pure a priori knowledge. Knowledge does not exist independently of the context in which it arises. That in turn does not, however, entail

that a problem can only be solved with one particular process of inquiry. Different inquiries can lead to similar practical consequences or result in an equally satisfactory solution to the problem.

There is always a human contribution to any form of knowledge as researchers are active participants in the making of our world. Researchers are never mere spectators; their thoughts and actions constitute the inquiry process of solving a problem. Pragmatism rejects all dualisms and therefore does not differentiate between knowing and acting—meaning that action is seen as a necessary component when acquiring knowledge, rather than as a contaminating factor. Problem-solving actions are based on existing knowledge, which after reflection results in new knowledge. This newly acquired knowledge is then the starting point for problems encountered in the future. This inquiry process is synonymous with the action research cycle and highlights the entanglement of actor, action and knowledge in the process of inquiry. For pragmatists, any knowledge claim is therefore simply a point of departure for the problem-solving process, not a definite solution. The focus on the problem to be solved, rather than the existing knowledge as such, makes pragmatism well positioned to deal with the complexity of modern research challenges, whether it is in science, social science or philosophy.

PRAXEOLOGY

Praxeology is a theory of human action or practice. Etymologically deriving from the Greek word *praxis* ('purposeful action') and *logos* ('word' or 'thought' or 'principle of knowledge'), the origins of praxeology lie in the concern of Greek moral philosophers, notably Aristotle, with knowledge in the service of human betterment, what we might now term *fulfilment* or *well-being*. Modernist applications of praxeology found expression in nineteenth century Austrian economics, twentieth century theories of learning and organization development through Action Learning as well as Pierre Bourdieu's praxeological theory in sociology. Essentially, praxeology can be understood as a theory of practical knowing.

The relevance of praxeology to action research is twofold. Firstly, there is shared concern that knowledge should serve practice and a core value that the point of understanding a situation is to change it. Secondly, praxeology and action research both place value on knowledge gained through action and the interrelationship between a researcher's developing self-knowledge and emergent insight into the organizational context. This entry provides an outline of praxeology's origins, traditions and key ideas. Contemporary ideas and applications are illustrated before concentrating on the particular relevance of praxeology to action research.

Origins, Traditions and Key Ideas

The basic principles of praxeology were first articulated by Greek moral philosophers, who applied them as a basis for a eudemonistic ethics, a concern with how knowledge might best bring virtue, happiness and flourishing, what in contemporary language we might now term *well-being*. For Aristotle, human well-being requires a combination of types of human endeavour, notably not just thoughts and contemplation (*theoria*) but also action (*praxis*). These types of human endeavour are differentiated by their related types of wisdom (*sophia* and *phronêsis*). *Sophia*, sometimes translated as theoretical wisdom, broadly equates to reasoning and rational learning, such as mathematics, science, logic, history and so on. *Phronêsis* refers to practical knowledge, the capability to act ethically, with wisdom based on experience. Praxeology, as a theory of action or practice, is the bringing together of knowledge and action, of contemplation and practice, equating to the Greek *sophia* and *praxis*, respectively. It can be understood as a kind of practical knowing. *Practice* in praxeology refers to knowing how not just knowing about. Knowledge is understood to be a 'learning from action', not a theoretical 'learning before action'.

This approach was further developed by the Scholastics, who extended praxeological analysis to the foundations of economics and social science. Western thought continued into the present day to be influenced by a perceived dichotomy between *theoria/sophia* and *praxis/phronêsis*.

In the late nineteenth century, a praxeological approach to economics and social science was reintroduced through Austrian economics, with the term *praxeology* first applied to this approach by the Austrian economist Ludwig von Mises. Praxeological economics is concerned with the study of purposeful human action in the course of consumption, in the sense of deliberately chosen behaviour by actors, such as preference, choice, creativity or incentives under a free market context. With a focus on how economic propositions came to be known, von Mises advocated a praxeological foundation to epistemology in economics, in contrast, for example, to mathematical economic models, with the rationale that without empirical testing, economic theories may be misconceived.

Contemporary Ideas

Within late-twentieth-century sociology, Bourdieu makes a particular contribution to contemporary praxeology with his theory of practice and the conceptual tools of habitus, field and capital, to make sense of social behaviour and the power dynamics of any social situation, including work organizations. 'Habitus' describes the constellation of inclinations, habits and ways of perceiving, understanding and behaving that an individual brings to social interactions. Individuals' habitus is strongly influenced by the resources, or 'capital', available to them by virtue of their social positions, including their socio-economic family background, geographical location, ethnicity and gender. 'Field' is a sphere of human activity, a context or setting. The extent to which individuals have influence over others in a particular setting, or field, depends on a combination of the resources (economic, social and cultural capital) they can draw on and the choices open to them within the norms and rules of the field.

Bourdieu's concern was to overcome the dualisms of structure and agency, as offered by Marxism, existentialism or phenomenology. Bourdieu's praxeological theory maintains that social life is always in relationship to multiple phenomena and that agents and agency are more than simply structurally determined cultural behaviours, which can be understood through the study of micro-practices in a specific context and in relation to the macro world of structural influences. This has clear relevance to action research, which engages study within a specific context of change and practice whilst

being concerned to contribute to wider knowledge and advance a wider understanding.

In relation to Action Learning, another action modality closely allied to action research, praxeology found expression in the work of Reg Revans, with his thinking on learning and his interlocking systems of action and learning: systems alpha, beta and gamma (Figure 1). System alpha focuses on the investigation of the problem, based on the managerial value system, the external environment and available internal resources. System beta focuses on the problem resolution, through decisions, cycles of negotiation and trial and error. System gamma focuses on the learning as experienced uniquely by each of the participants through their self-awareness and questioning. System gamma concerns the participants' cognitive framework, their assumptions and prior understanding.

The three systems, alpha, beta and gamma, are not linear or sequential, nor are they entirely discrete. They are perhaps best understood as a whole, whose interlocking yet overlapping parts were given differing emphases by Revans at different times. In Revans' articulation of praxeology, learning involves engagement with real issues rather than with fabrications. The engagement is both scientifically rigorous in confronting the issues and critically subjective through managers learning in action. Systems alpha and beta focus on the investigation of the problem, while system gamma focuses on the learning. System gamma invites connection to the manager's existing beliefs, assumptions and image of himself or herself. Implicitly, this is a systemic way of thinking of learning as an interplay between a manager's beliefs, actions and the results of

those actions. As managers engage in the investigation of a situation, experiment with possible resolutions and monitor the results, if they are also challenged to attend to their own prior assumptions and beliefs, they may well come to recognize that their perspectives are part of the problem and that they themselves must change some of their actions or beliefs if the situation is to be changed. Revans in fact suggested that it is the values of managers and the organization that are most likely to obstruct effective action and learning. Praxeology, as articulated by Revans, promotes the highest level of reflexive, systemic learning amongst those engaged, simultaneously to addressing organizational problems and improving professional or management practice. Praxeology in this sense can be understood as a growing mastery of learners over themselves as their mastery of their environment grows. Profound self-development comes from taking risks in the course of experimentation on tricky issues and from being challenged to be reflexive—to explore the relationship between the issue tackled and the actors themselves.

Application to Action Research

The reflexivity and systemic or relational thinking articulated in praxeology by Revans and Bourdieu are also seen as integral to action research by many traditions. Similarly, Aristotle's and von Mises' concern with praxis and pragmatic knowledge and research that can generate knowledge that achieves desirable, useful outcomes is reflected in action research. Praxeology is grounded in lived experience, just as action research is grounded in the lived experience of the researcher and the research participants. Action research shares the praxeological axiom that the point of understanding and interpreting the world is to change it.

The traditional and enduring structure/agency debate polarizes analysis of human behaviour and decision-making between, on the one hand, the argument that they are the result of agency, the ability or capacity of actors to act consciously and make their own choices, and, on the other hand, explanations that emphasize the role of social structures in shaping and delimiting individual agency. Praxeology in action research brings structure and agency together, integrating the recognition that structures are both the preconditions for participants' agency as well as the outcomes of that agency. In action research, participants become more agentic in the sense that they gain a stronger awareness of their own agency—that is, their ability to influence and act and shape their world. Yet simultaneously, through the reflexivity encouraged by action research, they gain an increased sense of the constraints within which they operate—the contextual influences structuring their agency.

Figure 1 Revans' Praxeological Science: Diagrammatic Representation of Three-Systems Model

Examples

Praxeology finds application in management education and development and organization development through the integration of action-based processes of learning so as to create a synthesis of theory and practice, grounded in real-world experiences through interaction with organizations. For example, learners may be encouraged to engage in a series of questions and conversations that mirror Revans' praxeology through corresponding with the systems alpha, beta and gamma:

- *Alpha*: What is the reality of my situation?
- *Beta*: What do I need to know more about? What do I need to test out? What is my inquiry methodology?
- *Gamma*: What am I learning about how I act in the situation? How does that knowing more about this change how I act and how I learn?

Participants are supported to challenge their assumptions, to work with ambiguity and contradiction, to acknowledge emotions provoked by the situation and the learning and to develop greater self-awareness of both learning about practice and learning through practice. The knowledge generated may remain within the organization or, in an action research tradition, may be connected and made more widely available.

Praxeological inquiry, meaning inquiry through purposeful action, is an emerging terminology in qualitative research. In common with action research, this approach uses and generates theories of action to reveal the underlying assumptions the researcher and the participants hold about their work and to elucidate why they do what they do. In common with Critical Action Learning, it engages participants explicitly with the power and micro-politics of the situation which they are trying to change.

PRAXIS

Action research concerns practice—that is, how research can be useful and relevant for practitioners and how practice is important for the research process and for theory. Hence, 'practice' is a central concept in action research. The following text outlines the roots of practice in praxis, how the original concept has been re-appropriated in the philosophy of the nineteenth and twentieth centuries and its relevance for action research.

The modern word *practice* is a derivative of the Greek original *praxis*. But they do not refer to the same thing. Since the late Middle Ages, the word *practice* has become part of colloquial English and other modern languages. Currently, the study of 'practices' has become a field of theoretical and empirical research. Still, many theorists choose to use the word *praxis* in order to distinguish it from ordinary *practice*. Colloquially, 'practice' means just about any kind of activity as opposed to inactivity, the way things are customarily done' or 'doing it' as opposed to just 'thinking it' theoretically. Praxis is a special kind of practice.

Original Praxis

In ancient Greek, *praxis* was associated with politics. But major institutional differences make politics in ancient republican city states different from its modern namesake. Originally, politics concerned actions, rights and duties connected to active citizenship—in other words, to citizen (*politês*) membership in the immediate community or *pólis* (city state). Today, political membership and eligibility are widened. But in spite of slavery being widespread, the inferior status of women and the privilege of ethnicity in delimiting citizenship, the ancient *pólis*, citizenship and politics were considerably more directly participatory and egalitarian for those (adult native males) eligible for full inclusion. Primarily, politics concerned the activities citizens or community members shared and had in common as peers, and so did praxis. Hence, in the thinking of Aristotle (384–322 BC), *praxis* became a technical term designating a particular way of knowing (*gnôsis*) based on a certain form of activity.

Currently, there are two major waves re-appropriating *praxis* from its original Aristotelian context. The first springs from Marx and Marxism in the nineteenth century, and the second from Martin Heidegger's reading of Aristotle in the twentieth century, from his students Hans-Georg Gadamer and Hannah Arendt and from Jürgen Habermas.

First Wave: Marxist Praxis

The starting point for Marxist attempts at distinguishing praxis is particularly Marx' *Theses on Feuerbach*—that is, from 1845. Here, Marx attacks the passive and receptive thinking of earlier materialism for leaving the subjective and active side to idealism, for over-focusing on contemplative (spectator based) theoretical activity and for not understanding human activity as material and sensual. Questions about truth are not theoretical, he claims (nor are they passively perceptual), but practical. Human beings are not merely determined passively by their circumstances. The circumstances themselves are created by human beings. This means that human beings can take conscious control. Reflectively and consciously changing themselves and their surroundings is revolutionary praxis according to Marx.

In subsequent thinking inspired by Marx, then, the conscious analysis and change of social conditions by the practitioner-knowers themselves transforms ordinary practice as mere predetermined execution or conventional performance into praxis. Hence, praxis implies or presupposes a special form of theoretical understanding in practitioners, penetrating, distinguishing and enlightening social conditions—expressing social conditions as human practices in ways that bring forth unrealized, immanent human potentials for shaping and reshaping both themselves and their surroundings. Among others, Paulo Freire has emphasized this element and made it explicit as reflectivity and conscientization through critical dialogue.

Strict Marxism focuses on changing the social world through the political struggle of the modern wage-earning working class. But Freire brings Marxist praxis close to action research—that is, to cycles of action research and Action Learning and to Kurt Lewin's epistemological dictum that 'you have to change it in order to understand it'. Both Marx and Lewin were inspired by experimental natural science in emphasizing active intervention as a precondition for understanding. This similarity to experimentalism points to distinctions missing or only vaguely expressed in Marxist praxis but emphasized in the second wave.

Second Wave: Phenomenological and Hermeneutical Praxis

The second wave of *praxis* re-appropriation focuses on the difference between praxis and *téchne* as different forms of activity. Heidegger and Gadamer both emphasize the concept of *phronêsis* and its immanence to praxis as their point of departure for modern phenomenology and hermeneutics, and for liberating human and social knowing from its subordination to

knowledge models imported from modern natural science, focusing on prediction and control. Arendt's distinctions between labour, work and action and Habermas' distinctions between technical, practical and emancipatory knowledge interests bring attention to an important difference between praxis and *téchne*, an important backdrop even for understanding the discussion between Marcuse and Popper about critical theory and social engineering. Critical theory evolved from Marxist praxis, while Popper's social engineering was accused of reducing social change to technique. The second wave of praxis re-appropriation emphasizes that understanding human and social relations cannot be done by modelling social science on natural science as political arithmetic or social physics or, consequently, as social engineering. This second wave distinguishes between *episteme* ('science'), *téchne* ('technique') and *phronêsis* ('practical wisdom'), all of which hark back directly to Aristotle's thinking about knowledge.

Aristotelian Praxis and Other Ways of Knowing

Aristotle singled out praxis as one form of *hêxis/habitus* or *gnôsis*—a 'way of knowing'—among several others, distinguished by (a) their different relationships between the knower and the known, (b) the location of the principle of change in the object known and (c) the different relationships between starting points, means and ends. Major terms besides *praxis* ('doing'), designating different ways of knowing along these dimensions, were *poiêsis* ('making'), *chrêsis* ('using') and *pathos* ('being passively influenced from without'). These basic ways of knowing could all be tacit (*álogos*). They could also be articulated, however, through corresponding intellectual virtues or ways of reasoning, like *téchne* ('calculation'), *phronêsis* ('deliberation') and *episteme* ('deductive demonstration'). *Episteme* represented mainly a non-intervening theoretical knowing, made up of *theôria* ('insight') or *theôrêsis* ('spectatorship'). To distinguish praxis, these other ways of knowing must also be outlined.

Other Ways of Knowing

Generally, in *poiêsis*, *chrêsis*, *pathos* and *theôrêsis*, the knower and the known are separate and external to each other, but their ways of interacting are different. In praxis and *theôria*, this relationship is internal as they tend to coincide.

In *poiêsis*, or making, the known is positioned as external material to be manipulated and changed according to the preconceived plans and ideas of the knower, as when a carpenter makes chairs and tables out of wood. The change is artificial, imposed from

the outside by art or craft. It is not natural, as when wood grows from a sprouting bud and then dies and deteriorates. In *poiêsis* relationships, the principle of change in the known is located in the knower, not in the known. Also, the end of *poiêsis* is a product—an artefact—separate from the maker and the process of making. The end of *poiêsis* lies outside *poiêsis* as an activity.

In *khêsis*, or using, the known is positioned as an instrument. Although the known is still manipulated according to the knower's preconceived plans and ideas, its qualities are not intentionally altered as in *poiêsis*. Yet the principle of movement and change in the known is outside it—in the knower (user). The instrument's movement is not natural. It has an external source. In both *poiêsis* and *khêsis*, then, the relationship between means and ends is external. The end of *khêsis* is also mostly outside itself (Aristotle distinguishes between instruments of *poiêsis* and instruments of *praxis*). There is no formal identity or similarity between starting point, means and end. In *poiêsis*, the transformed materials may remain in the final product. In *khêsis*, the instruments do not. Both *khêsis* and *poiêsis* are heterotelic; their end is separate, external to and different from the activity of *khêsis* and *poiêsis*. When the end is achieved, both activities stop. The activities of *khêsis* and *poiêsis* carry no intrinsic value. Both constitute artificial intervention competencies related to external objects, mostly carried out for getting something or somewhere else, not for their own sake.

Pathos concerns the known in *poiêsis* and *khêsis* relationships. Instruments or materials suffer pathos by being passively manipulated by users or makers. Hence, if conscious beings enter these positions as materials or instruments, their way of knowing would be pathos. The relationship is still external between the knower and the known. Pathos is knowledge derived from suffering, from being used or manipulated. The knower is passively affected by the known. Being subjugated under the power of others is pathos, and so is being under the sway of your own emotions. Even sense perception is a form of pathos, since we cannot but sense whenever an object is within the range of perception. Pathos is the knower's knowledge as she or he is affected from without.

Theôresis reverses this direction of attention focusing on the external object. The knower and known are still separate, distant and externally related. In the previous relations, there is interactivity between the knower and the known. In theôresis, there isn't (not even emotionally or by pathos). The knower is a spectator without the possibility or the legitimacy to influence, or to be non-cognitively influenced by, the known. Theôresis leaves the known object as it is.

Hence, the principle of any change or movement in the known resides in the object itself, not in the knower. The known moves or changes naturally, from within, not artificially from without as in *khêsis* and *poiêsis*. Thus, the knower is relegated to informed and intelligent guessing—creating analogical hypotheses and models—about what creates movement and change, and how and why. Theôresis describes the position of the knower in astronomy. Hence, this model of knowledge (together with *poiêsis* as a model for experimentation), and its specific ways of testing, validation and falsification, has had a profound historical influence on our modern thinking about science and research.

Praxis

In *praxis*, the relationship between the knower and the known, the location of the principles of change and the relations between starting points, means and ends are different from the previous forms. In a *praxis* relation, there is no object to be known outside the knower. The object is an internal objective. The known is in the knower. The end of *praxis* is not a separate external product as in *poiêsis* but rather excellent *praxis*, or *eupraxia*. *Poiêsis* makes things, *praxis* makes perfect! In *praxis*, the knower and the known tend to coalesce in bringing current *praxis* to coincide with its internal standard of excellence in *eupraxia*. As in *khêsis* and *poiêsis*, the knower is responsible for movement and change. But while the previous forms are heterotelic, *praxis* is autotelic, carrying its end within itself. Hence, in *praxis*, the location of the principles of change in the known—the whats, hows and whys of our own acting—is in the knower, but it is also in the known.

In the previous ways of knowing, the knower and the known, the principles of change and the starting point, means and ends are allocated to different positions. In *praxis*, they all coalesce. There is no formal separation or difference between starting point, means and end. As in learning a language, the novice piano player does the same thing formally as the one practising for perfection and the virtuoso performer. In the Aristotelian scheme, the development or improvement is a quantitative growth in capability through *praxis*, from abstract to concrete potential. Although each way of knowing requires its specific relation of user, maker, sufferer, spectator or doer to develop, this aspect of *praxis* also makes it common to all the previous ways of knowing. There is a *praxis* dimension to every way of knowing, through which we move from novice to expert in its specific knowledge relationship.

Praxis also singles out an *ethical* sphere of our existence. *Poiêsis* and *khêsis* hardly have inherent

value. Having their end beyond themselves, they are mere means. But certain kinds of activities are not merely means. What Aristotle called ethical virtues or excellences of character carry their ends inherently in themselves. All ethical virtues are *praxeis* like this. Justice is such a praxis virtue. Praxis is not just an aspect of justice, as it is in using means and manipulating materials. Justice is not a mere means for something else. It is an end. Courage is another such ethical virtue. So are truthfulness, wisdom, friendship, happiness as functioning well and others.

There are both technical and ethical virtues. Aristotle differentiates them thus. In technical virtues, a voluntary error is not as bad as an involuntary error. If you make a deliberate mistake in singing or playing an instrument, this may merely prove your complete mastery of the art. Not so with the ethical virtues. In ethics, a voluntary mistake—being deliberately unjust, unfriendly and so on—is worse than an involuntary mistake of being unknowingly unjust. Forgetting a technical skill is not generally considered blameworthy. But forgetting to be just or courageous is blameworthy. An ethical virtue is a habituated inclination (*héxis/habitus*) to act and feel correctly, not only for the right reason, since things can be done in a formally correct way by chance, technically or under the influence of others (by mechanical rule following or following orders). To count as virtuous, acts must be done with a right reason or justification. *Phrónêsis* is a right reason in these matters, according to Aristotle.

Theory and Praxis

The different ways of knowing have specific intrinsic ways of reasoning. Syllogistic deduction belongs to the presentation of finished episteme, *téchnê* ('calculation') belongs primarily to *poiêsis* and *phrónêsis* ('deliberation') belongs to praxis and the ethical virtues. These will not be dealt with here. But something must be said concerning theory and praxis. According to Aristotle, theory is knowledge based on a non-intervening relationship with the known, letting the objects of study remain, unfold and develop as they are naturally. The principles of change and movement in the known reside in those objects themselves. Theoretical knowledge is merely distinguishing, descriptive and analytical. This includes more than merely episteme, however. Perception is theoretical in this sense. But intermediate ways of knowing like *poiêsis* and *khêsis* are not, since the knowers actively impose their own principles of change on the objects known and since their immediate aim is some form of activity.

But praxis, or the result of praxis as an inner object—a *pragma* ('thing') or *empeiria* ('experience')—remains as the basis for a form of theory, *theôria*, different from *theôrêsis* since, as required for theory, the principles of movement in praxis reside in the object known—that is, in the knower, in the inner *pragma* and in the internal objective of *eupraxia*. The standard of *eupraxia* is not strictly predefined but emergent, and the building and unfolding of practitioner potential through praxis, developing from the fumbling and inchoate amateurism of a novice to professional and virtuous/virtuoso practice, is not external intervention but similar to natural growth. But unlike the study of external nature (*theôrêsis*), the knowers are inside both praxis and *pragma*, or they are inside us as knowers. Hence, in praxis, we are responsible for movement, change and development.

Historically, astronomy is a paradigm of spectator-based theory (*theôrêsis*). Grammar is more suitable as a paradigm for a praxis-based *theôria*, or insight. The relationship between the knower and the known is widely different in these disciplines. Grammar articulates a reasoned practice and competence structure from within, and it transforms this into conscious and self-conscious praxis of and for the knowers-practitioners themselves. Applying the model from astronomy, however, divides society into two parts, one of which towers above (as spectators), as Marx writes in the third thesis on Feuerbach. Aristotle made deduction the paradigm of a finished episteme—in other words, the didactic presentation of a finished body of knowledge. But the inductive development of insight, understanding and competence as aims and ends in themselves (from novice to expert) was to be done dialogically through praxis—just as theoretical as deductive-didactic presentations—however, since developing competence and insight does not have an immediate or particular act or product as its aim. Its end is general. The perfection of praxis emerging and growing into *eupraxia* had two aspects: (1) *praxis*₁—the building of general competence or virtue and insight, guided by critical dialogue, and (2) *praxis*₂—the performative perfection of singular, ethically virtuous acts here and now, guided by *phrónêsis*.

Grammar brings us back to the intrinsic relationship between praxis and politics. Grammar we have in common and share as peers—in other words, it provides internal standards we all relate to, stretch towards and grow into as equals practically, even if some are novices and others virtuosos. This relationship also provided the standard for Aristotelian politics among the eligible in the ancient city states. Praxis carries the standard for political communities

within itself: community, equality and freedom. Its emphasis on conscious and self-conscious practice provides a model for a different kind of psychological, educational, social, organizational, economic and political theory, developed from within real and mundane subjectively experienced and articulated practices like Marx required, as action research and a methodology and ethics for knower-practitioners studying their own practices from inside, not as theoretical models emulating the natural sciences in attempting to study everything and everyone as observed, manipulated and controlled external objects.

PROCESS CONSULTATION

There are many different forms of helping or consultation, from expert-based advice to process-focused facilitation. *Process consultation* is a term developed by Edgar Schein in the 1960s as his contribution to the development of organization development theory and practice. Process consultation is an approach to helping. It is defined as the creation of a relationship with the client that permits the client to perceive, understand and act on process events that occur in the client's internal and external environment in order to improve the situation as defined by the client. While its origins are in the organizational domain, it may be utilized by managers, parents, colleagues and friends as a way of helping others to think out and work through their own issues. This entry introduces process consultation, compares it with other approaches to helping and discusses diagnosis and intervention and process consultation's relationship with organization development and action research.

Helping Models

Schein locates process consultation in juxtaposition to two others approaches, what he calls (1) the doctor-patient model and (2) the purchase model. The doctor-patient model of helping is predicated on the familiar process of an individual experiencing pain and going to a doctor, who performs a diagnosis and prescribes a remedy which the individual implements. This form of helping—in other words, drawing on the knowledge of experts—is both common and useful. For this approach to work properly, several elements have to be in play: (a) the individual or client needs to reveal the necessary information for a good diagnosis, (b) the expert needs to have the necessary expertise for diagnosis and prescription and (c) the client has to accept the diagnosis, to implement the prescription and remain healthy afterwards. In the purchase model, the client purchases the skills of the expert. Here too, it depends on the client identifying the problem correctly so as to engage the relevant expert and impart the relevant information in order that the problem may be solved in such a way that the client accepts what the expert has done and remains healthy after the expert leaves. The organization equivalents of these two forms

of helping are (a) when external experts are brought in to perform an analysis and to write a report with recommendations for organizational action or (b) when external expert skills are brought in to design and install technology or other systems.

In keeping with the definition provided above, process consultation focuses on building a collaborative relationship between consultant and client so that the client sees what is going on, develops some understanding and builds a plan to take action. It is based on the underlying assumptions that (a) managers often do not know what is wrong in an organization and so need a special kind of help to understand what their problems actually are and (b) they often do not know what kinds of help consultants can give and so need help in knowing what kind of help to seek. They need help in being able to identify what needs improving and what does not. They may want to solve the problems themselves, but they need help in deciding what to do. Accordingly, process consultants need to have skills in establishing a helping relationship, knowing what to look for in an organization and intervening in such a way that organizational processes are improved.

Diagnosis and Intervention

In expert-based models, diagnosis is done by the expert as an antecedent to intervention. In process consultation, diagnosis and intervention are simultaneous processes as the process consultant engages the client in trying to understand what is going on and why. In process consultation, diagnosis is done by the client, and it occurs through the process consultant's interventions. In process consultation, the consultant is never just diagnosing but is always intervening, even when being silent. The process consultant asks questions and makes comments which aim to be helpful in structuring the client's thinking further and reveal information about what is really going on, thereby teaching the client how to look at his or her own information and analyze it. A key tacit process is that the process consultant is communicating to the client that he or she is willing to help but not take the problem onto his or her own shoulders.

What is central, therefore, to the theory and practice of process consultation is the focus on and skill of learning how to be helpful. For the process consultant, this involves recognizing the limitations of expertise and attending to how to be helpful. So there may be occasions when a particular expertise is needed by the client, and the process consultant may offer that expertise. Schein's advice is to begin in the process consultation mode—that is, with a spirit of inquiry. When one begins as the expert, it is difficult to step out of it,

while beginning in the process consultation mode and remaining firmly in it allows the process consultant to step into an expert role when the occasion demands and then step out of it.

Process Consultation and Organization Development

Process consultation lies at the heart of the values underpinning organization development. The core value is how employees discuss and analyze critical issues for change and find and implement solutions and evaluate the outcomes. Process consultation is a philosophy of helping that enables clients to understand and resolve their own problems. As such, process consultation constitutes authentic organization development.

Process Consultation and Action Research

Process consultation has a close relationship with action research in several ways. Firstly, the notion of process consultation grew out of Schein's reflection on his own experience and so emerged from an action research mode. Secondly, its way of working reflects the values of the collaborative mode of working that action research espouses, where participants are facilitated to understand their own context and so are helped to design and implement their own strategies and actions. Thirdly, and more explicitly, process consultation is equivalent to Clinical Inquiry, which is a mode of action research built on the assumption that the researcher is invited into an organization to help (and be paid for it) and that diagnostic and intervention activity is aimed towards enabling the system to function more healthily.

PROJECT MANAGEMENT

The project environment is often referred to as a ‘temporary organization’ where social interactions occur to deliver projects. The aim of a project is to deliver a unique outcome that solves a problem for a client within a specified time frame. Action research, with its foundations in social enquiry, provides a complementary approach to solving problems using iterative feedback cycles. In both project management and action research, there are prescribed cycles to conceptualize, plan, implement and close the work being undertaken. These action research cycles suggest a linear or single-loop approach, as in the application of the project management methods PMBOK, PRINCE2, and Logframe. However, the action research approach can also include multiple cycles of problem-solving activity to address a research issue, which is represented in the overlapping cycles of the Agile project management method.

The action research cycle is based on a continuous feedback loop that requires ‘actors’ to plan, act, observe and reflect in order to be able to identify variations and then manage them. The ‘actors’, or project managers, are involved in this collaborative inquiry to work systematically to evaluate their actions through a self-reflective spiral that informs future action cycles and also ‘spin-off’ cycles. These action research cycles can also be defined by the type of research project. For example, if the outcome is known, a technical approach may be appropriate; if the project drives the action, then a practical approach may be required; and if all participants play a role, then the research project may be defined as critical.

The subjective interpretation of information in action research, as with project management, can be classified as ‘idiographic’ as the work undertaken may not be objective, although interpretation of data and experiences can rely on multiple sources of information. The project manager and the action researcher have an opportunity to then test and explain any emerging deviations or themes that may contradict the expected outcomes and prior analysis of data.

Project Management History

Project management was described in terms of ‘scientific management’ in the late 1800s, when the early workflow tools were introduced. Throughout the early 1900s, a series of refinements were made to these tools, and by the 1970s, the project office emerged to provide the much needed oversight. In the 1980s, there was a wider acceptance of managing strategic and organizational change through project management methodologies which required a refocus on stakeholder identification,

environmental impacts and life cycle costing. The acceleration of change in the 1990s, driven by the introduction of the personal computer, provided the technology to manage a variety of project types across organizations. In the 2000s, the development of global strategic alliances provided an opportunity to collaborate across industry and across geographical boundaries.

Project Management Methods

To manage a project, the project manager can use several different project management methods, as is the case for the action researcher when deciding on the most appropriate type of action research method for the research. The selection of an appropriate project management method depends on the type of project, the organizational mandate or the project manager’s preferred method, or it might be a combination of several methods. The four project management methods that are most commonly espoused by governments, professional associations and industry are ‘A Guide to the Project Management Body of Knowledge’ (PMBOK® Guide), ‘Projects IN Controlled Environments 2’ (PRINCE2), the ‘Logical Framework Approach’ (LFA or Logframe) and ‘Agile Project Management’.

PMBOK® Guide

The PMBOK® Guide, now in its fourth edition, was first published in 1996 by the Project Management Institute and describes a set of standard project management terms, processes and knowledge areas. The processes describe how a project is initiated, planned, executed, monitored and controlled and closed. The knowledge areas define a project according to the (1) elements of integration, (2) scope, (3) time, (4) cost, (5) quality, (6) human resources, (7) communications, (8) risk and (9) procurement. During the management of a project, the PMBOK® Guide provides an outline for the inputs, tools and techniques and outputs for each of the nine knowledge areas.

PRINCE2

The basis of the PRINCE2 method was developed by the UK government in 1989 for information technology projects, and it was further developed into a generic project management method in 1996. The PRINCE2 method is based on seven processes that describe a project in terms of (1) start up, (2) initiation, (3) direction, (4) controlling stages, (5) managing stage boundaries, (6) managing product delivery and (7) project closure. The techniques described in the PRINCE2 method include product-based planning, change control and quality review. Within these processes, the PRINCE2 method espouses principles that include the business

case, organization, quality, plans, risk and change progress. In addition, the themes cover continued business justification, learning from experience, defined roles and responsibilities, managing by stages, managing by exception, focusing on products and tailoring to suit the project environment.

Logframe

Logframe is a document that is used within the Logical Framework Approach project method, which was introduced in 1969 for the United States Agency for International Development to design, monitor and evaluate international development projects. To measure the progress of a project, Logframe relies on a 'temporal logic model', which requires the project manager to first identify and then connect project classifications. These project classifications include the description; objectively verifiable indicators, means of verification based on the objectively verifiable indicators and positive or negative assumptions according to the projects goal, purpose, outputs and activities.

Agile Project Management

The Agile project management method evolved in the 1990s as a reaction against the highly regulated software development project management methods from the 1970s, such as the Waterfall Development Model. The Agile method relies on collaboration between cross-functional teams that self-organize to rapidly respond to change when determining requirements for software development and engineering projects. This method is iterative and requires a flexible approach to overlapping project phases when deliverables have been completed, often in very short time frames. In direct contrast, the Waterfall Development Model, adapted from the manufacturing and construction industries, follows a sequential order of project phases, where each preceding phase must be completed before moving to the next phase.

Rethinking Project Management

An increased level of project complexity saw the acceleration of project failures, suggesting that the traditional project management tools and methodologies were inadequate. In 2006, a prominent project management research initiative was undertaken to identify how to manage project complexity and increase project success. A network of academics and senior practitioners from private, public and volunteer organizations in the UK, Canada, Europe, the USA and Australia was formed to undertake this research in response to the concerns of project managers in the areas of project complexity, social process, value creation, project

conceptualization and practitioner development. To include input from a wide range of perspectives, a learning system model was adopted by the network to set the research agenda using a process of inquiry. The concept of organized sense making was used to establish how formal meetings and additional work would focus on the core areas of concern. The iterative research cycles, representative of an action research approach, provided the network with a framework in which to produce papers on the perceived issues and themes from the meetings. Three key directions were identified and presented in the form of theories *about*, *for* and *in* the practice of project management. These directions provided recommendations on how to deliver value using social practices in a project context.

The processes and methods used to manage a project can be applied when undertaking an action research project. In setting up an action research project, the researcher will need to understand the organizational context when identifying and working with research participants and validation groups. Agreement on how the research will be undertaken and a common language need to be established before a plan to do the research is agreed on. The plan will need to include (a) the scope of the research project, (b) where information will be sourced, (c) who will work on the project at various times, (d) how the project will be financed and (e) a schedule of when the work will be done. Confidentiality needs to be ensured in the collection, use of, storage and retrieval of data. The design of an appropriate action research method needs to be guided by an existing framework that is flexible, to allow for changes after a review or intervention has occurred. At the conclusion of the action research project, the researcher needs to have the resources to analyze and document the findings and provide an evaluation of the project to document future improvements and areas for further research.

The process of undertaking an action research project described above is not dissimilar to the process that a project manager would follow to deliver a project. The social interactions and interventions that a project manager uses to achieve an agreed outcome with the client follows a method selected to suit the type of project and context. Agreement with the client on the scope of work and the resources that will be engaged to complete the project sets the framework for delivering an agreed outcome. The project manager will negotiate the budget and time, balanced against the expectations of quality, at the same time ensuring that the communications are appropriately managed. When change occurs, the project manager will assess the impact based on the agreed risk tolerance and throughout the project will keep the validation group, often referred to as a steering committee, informed of the

progress and seek advice as required. When the project has been delivered, a review and evaluation of the outcomes will be captured and recommendations made for future projects.

Both project management and action research aim to solve real-world problems using iterative cycles of action and reflection through a collaborative and appropriate method. Therefore, action researchers and project managers may benefit from sharing and comparing their respective approaches to the management of their work. The increased level of complexity in projects and the need to provide a higher level of clarity around the action research process suggest an overlap in these two practices.

QUALIMETRICS INTERVENTION RESEARCH

The qualimetrics methods were created in the early 1970s by Henri Savall and his colleagues at the Socio-Economic Institute of Firms and Organizations (Institut de Socio-Economie des Entreprises et des Organisations, ISEOR), a research centre associated with the Jean Moulin University Lyon 3 and E. M. Lyon (École de Management de Lyon) in Lyon, France. At first, it is necessary to define qualimetrics intervention research. It is a specific Intervention Research methodology aimed at triggering a common representation system shared by all the actors of an organization through the use of qualitative, quantitative and financial data. On the face of it, qualimetrics intervention research shares the same sociological and anthropological roots summed up in the concept of ‘participative observation’, a method which consists in carrying out observations by participating in productive activities. As in action research, in qualimetrics intervention research, researchers are at the same time partners as regards companies’ observation and co-producers of knowledge with company actors. Intervention researchers when applying a qualimetrics methodology adopt a decidedly transformative approach towards the research object, as the objective is to change the structures and behaviours observed in the company or the organization by experimenting both on and with the actors so as to better understand the phenomena observed ‘through and for action’. Like in action research, the objective of qualimetrics intervention research is to create a community of inquiry. However, qualimetrics is focused not only on the creation of such communities of inquiry regarding social phenomena but on a more comprehensive analysis of the organizations that takes into account both social and economic performance. Indeed, most action research and Intervention Research methodologies find their common origins in sociology and not in the field of

accounting or economics. Conversely, the qualimetrics methodology as a measure of performance is seen as more efficient than classical quantitative measurement as it seeks to reconcile the three opposed logics systems—qualitative, quantitative and financial—by recontextualizing them so as to circumvent a silo type of approach and to get a clear picture of their interaction.

Qualimetrics methodology assumes that accounting only gives a partial representation of a company’s overall economic performance. Traditional accounting is the realm of number crunchers. The rigidity of numbers (which, moreover, can be tampered with or selectively manipulated, as evidenced in the ethno-statistics approach) can lead to distorted images of organizational performance. Conversely, what is often referred to as the magic of words can also be misleading. To reconcile these opposite approaches to the bottom line, the qualimetrics modelization permits bringing meaning to both words and numbers. Qualimetrics is thus defined as an intervention into the way in which numbers are produced, analyzed, displayed and interpreted.

Epistemological Underpinnings

The qualimetrics intervention research approach mobilizes the following three concepts or principles.

Cognitive Interactivity Principle

First, the cognitive interactivity principle is an interactive process of knowledge production between company actors and intervener-researchers through successive feedback loops, with the steadfast goal of increasing the value of significant information processed by scientific work. In other words, several interviews and meetings are organized to help actors be more accurate with regard to the dysfunctions to be addressed. It partly draws on a constructionist epistemology as it considers that the complex object is difficult to grasp in its entirety. It therefore differentiates from positivist research, which seeks so-called neutrality: Action

researchers and qualimetrics researchers alike are interacting with actors. Cognitive interactivity leads to two types of results:

1. For company actors, it modifies their viewpoint on the operation and performance of the enterprise as well as their behaviour in the workplace; they are led little by little to modify their representation of the research object.
2. For intervener-researchers, it brings out new facts which allow them to strengthen existing hypotheses or to express new ones, thanks to the additional qualitative, quantitative and financial data provided by the qualimetrics approach.

Contradictory Intersubjectivity Principle

Second, the contradictory intersubjectivity principle is a technique for creating consensus based on the subjective perceptions of different actors in order to create more objective grounds for working together through the numerous interactions between the actors. It thus consists in confronting the points of view of all the actors, the objective being to identify specificities and convergences and to reconcile different or conflicting logics within the enterprise. It avoids the limitation of a purely conceptual model of action: lack of rigour in inquiry method and in applying validity procedures. Multiplying different images of or perspectives on company operations improves the quality and the significance of the information captured, hence the necessity to collect information from diversified and multiple pools of informants, since confronting subjective representations results in the production of a new, collective representation and sensemaking. They are indispensable in the context of change entailed by the qualimetrics methodology.

Generic Contingency Principle

Third, the generic contingency principle designates the epistemological principle that, while recognizing the operational specificities of organizations, postulates the existence of invariants that constitute generic rules, embodying core knowledge that possesses a certain degree of stability, universality and reproducibility. Knowledge produced by intervention researches tends to be specific, and hence contingent by nature, but the contribution of the qualimetrics method is to help bring to light fairly permanent features and invariants, thanks to the scientific programme stemming from the exploitation of a database in which are collected the results obtained through intervention researches carried out by ISEOR in hundreds of companies and organizations throughout the world, constituting a highly reliable statistical

series. This is why the qualimetrics methodology is construed as 'a generic knowledge construction instrument'.

Those epistemological tenets have enabled the building up step by step of a generic knowledge creation now explicitly referred to as the 'socio-economic approach to management'. Indeed, the qualimetrics intervention research methodology unveils the infra-micro relationships between the economic and social performance factors, as opposed to only focusing on either economic or social performance.

The implementation of the qualimetrics method has resulted in the design of participative management tools, as opposed to widespread centralized and authoritative management tools. Those tools are aimed at promoting development and facilitating decision-making.

Internal and external action plans consist of 3- to 5-year master plan listing and prioritizing the strategic initiatives to be taken for ensuring the development breakthroughs. This strategic action plan involves each and every actor throughout the organization and is consequently participatory in essence, as opposed to traditional strategic planning. In accordance with the qualimetrics approach, one major objective is to enhance awareness of the hidden costs resulting from dysfunctions and the conversion of hidden costs into value added with a view to avoiding loss of energy and removing obstacles to the firms' strategic development internally and externally.

Priority action plans are implemented half-yearly and are meant to identify the high-value-added development actions as against the low-value-added ones, to help attain strategic objectives as advocated by the qualimetrics approach and prevent dysfunctions. This participative tool is meant to involve all team members in order to reconcile participation and co-ordination. This phenomenon goes by the name *decentralized synchronization*.

The competency grids are synoptic tools displaying the competencies of each and every company actor. This grid is designed through communication, co-ordination and co-operation so as to come up with a shared vision of the existing skills and the integrated training required for job enrichment and career prospects development as well as multi-skilling. They play a pivotal role in qualimetrics research intervention when it comes to drawing up a bottom line which would avoid the usual fragmented approach between economic, social and ecological performance metrics and which would allow one to link them by shedding light on the interactions between those three factors. It helps in analyzing the ratios featuring on balance sheets and in accounting for the dysfunction costs resulting from lack of skills or wrong job specifications. The grid actually

deals with the intangible assets of a company or an organization partly or totally left out in accounting documents and thus contributes to obtaining the proper qualitative, quantitative and financial evaluation specific to the qualimetrics approach.

Socio-economic logbooks are used as opposed to traditional accounting and management control documents. This set of indicators broadens the scope of economic and social performance measurement by embracing not only short-term performance but also the creation of potential—in other words, long-term performance. It contributes to changing organizational roadmaps by better balancing short- and long-term qualitative, quantitative and financial results elicited by the qualimetrics approach. It thus enables organizations to better achieve sustainable development.

The qualimetrics methodology enables the measuring of impacts of dysfunctions (qualitatively, quantitatively and financially) translated into hidden cost (or loss of value added). It helps in identifying and quantifying hidden costs which are rarely or never mentioned in a company's traditional accounting information system. Capitalizing on the results of 34 years of international research in 35 countries around the world made it possible to describe different categories of dysfunctions within companies and organizations, classified under six headings: (1) working conditions, (2) work organization, (3) communication-co-ordination-co-operation, (4) time management, (5) integrated training and (6) strategic implementation.

The intervention researchers when implementing the qualimetrics approach proceed to a monetary assessment of the hidden dysfunctional costs by evaluating the costs linked to five major indicators: (1) absenteeism, (2) occupational injuries, (3) staff turnover, (4) non-quality and (5) direct productivity gaps. They are, at this point, in a position to bring to light and evaluate the chief components of the financial consequences of dysfunctions: excess salary, excess time, overconsumption, non-production, non-creation of potential and risk.

At the end of the qualimetrics intervention process, improvements are evaluated financially by measuring the transformation of hidden costs into value added. Indeed, the objective of the qualimetrics intervention is to operate the conversion of hidden costs stemming from dysfunctions into value-added creation. The gains in value added actually identified are compared with the cost of the research actions, which permits establishing the actual economic balance as well as assessing the profitability of the change actions implemented by the enterprise. Those economic balances are determined by taking into account the investments and the subsequent improvement in performance in terms of increased value added.

Conclusion

The contribution of the qualimetrics methodology to action research processes is, on the one hand, to break the silo between social and economic objectives. On the other hand, this method demonstrates that action research projects are important not only for social reasons or to enhance reflexivity and organizational learning but also because they can result in sustainable economic development: the qualitative, quantitative and financial evaluation of the metamorphosis of dysfunctions and hidden costs into added-value creation and performance improvement is done in terms of both immediate results and creation of potential.

The qualimetrics intervention research is aimed at enhancing the quality of scientific participative observation in the field of organizational change. Indeed, such a scientific object is difficult to grasp because it is intangible, complex and ever-changing. It requires eliciting implicit variables, which can be achieved only through research methods that enable in-depth and up-close observation of the research object. Such a scientific observation methodology needs to analyze the organizational change phenomena from different points of views so as to better analyze the multifaceted scientific object. Such a challenge can be overcome only by involving a research team consisting not only of the intervener-researchers but also of the organizational actors, who are in a way 'scientists in the raw'. For example, the ISEOR laboratory took the initiative of organizing yearly conferences where intervener-researchers along with company actors present the outcomes of the research processes, as opposed to a more traditional 'ivory tower' practice.

Another difference with other forms of action research practices is the concept of generic contingency (see above), which can be illustrated by the implementation of co-built management tools, as opposed to more informal organizational learning processes.

QUALITY

Action researchers conduct their participative inquiry *with* people who are the stakeholders to the issues and inquiry at hand. This orientation to inquiry is found most frequently in efforts aimed at improving social systems—in other words, those complex meeting places where our human reality as social and biological creatures intersects with behavioural and technical systems, giving rise to politics. Action researchers strive for rigour, but not at the sake of the vigour of the work together. Assessing the quality of timely action in behaviourally and technically complex situations therefore requires a way of conceptualizing quality that goes beyond conventional notions of validity. A new understanding of quality is emerging that is informed by conventional notions of validity but that necessarily moves beyond its limitations. Because action researchers acknowledge the complexity of social phenomena, we emphasize multiple dimensions of quality, which are offered as choice points to guide collaborative action.

Multiple Dimensions of Quality

Action research, although not easily defined, is described as a participatory, democratic process concerned with developing practical knowledge in the pursuit of worthwhile human purposes. Peter Reason and Hilary Bradbury describe it as bringing together action and reflection, theory and practice, in participation with others, in the pursuit of practical solutions to issues of pressing concern to people and, more generally, the flourishing of individual persons and their communities. Action research therefore seeks to interweave what is often kept separate, thereby honouring unity and diversity, leading to a multidimensional terrain of endeavour.

Timely action with people in social systems at this moment in history means a willingness to engage with unprecedented challenges of sustainability that are interrelated and compounding. Challenges include complex issues such as poverty and injustice, patriarchy, climate change, the degradation of nature,

globalization, inequalities and fundamentalisms of all types. Conventional science and its conduct are part of these problems. Far from being the enterprise of a lone researcher, action research engages local stakeholders—particularly those traditionally excluded from the research process—in problem definition, research processes, interpretation of results, design for action and evaluation of outcomes.

There has always been tension with regard to how objectivist we ought to be in the development of knowledge. Kurt Lewin, often considered the founding father of action research, exemplified a hypothesis-testing approach. John Collier, Lewin's colleague, who actually coined the term *action research*, advocated a more democratic collaboration in the treatment of important social issues. Contemporary action research continues to hold this tension. Yet in the light of serious efforts to integrate the insights since the post-Lewinian linguistic and pragmatic turns—insights largely ignored by conventional social science—Collier's original vision appears to be in the foreground today.

Beyond the Cartesian Split to Integrating Linguistic and Action Turns

Orlando Fals Borda has claimed that action research is the most natural form of inquiry known. Dawn Chandler and William Torbert go as far as to assert that it is ubiquitous, especially in its embrace of future considerations as a part of inquiry, rather than documenting only what has safely passed. Indeed, for most of history, most people in most parts of the world have been practical and time sensitive in their efforts towards knowledge generation. That is, until the great Cartesian split—the split between reason and intuition, mind and body—that resulted from the implications of a world view that primarily and solely privileged a search for objectivity. The resulting conventional knowledge is therefore evaluated according to internal and external validity, reliability and its generalizability. Bjørn Gustavsen has quipped that conventional research is concerned only with being 'very right'. In most social science studies, this 'rightness' is garnered by focusing on as narrow a segment of reality as possible, with the cost of discounting most of lived reality. The circumscribed concerns of validity are simply unsuitable to the broader aims of action research, which include helpfulness to its stakeholders, insight for practice at the personal, group and larger systems levels as well as social transformation.

Action researchers' concern for 'quality' is similar to the concern that 'validity' plays in conventional science. At this moment in the unfolding philosophy of science, action research is unique in its integration of objective-empirical with subjective and pragmatic

orientations. Our integration of the subjective is informed by the ways in which we now understand that experience is mediated by cognition and language. Referred to by Richard Rorty as taking ‘the linguistic turn’, action researchers acknowledge that language fundamentally shapes what is knowable about phenomena. But simply knowing is not enough. Action researchers stretch to the action turn because we understand that social reality is profoundly relational and that the co-ordination of action is at play among us. Thus, the motivation for knowledge creation is not so much simply to know what is true, for the sake of objective, disembodied truth, but rather to accomplish something of mutual value. As a consequence, validity is enhanced with the multidimensional considerations that spring from a potentially deeper integration of subjectivity and pragmatism with objectivity, or more properly, partial objectivity.

Reimagining quality from an action research perspective therefore invites us to think of action research as a way to access much more than the narrow slice of reality addressed by conventional social science methods. It is also to note that even conventional social science has slipped from the vision that its founding luminaries, such as Adam Smith, David Ricardo, Karl Marx, and Max Weber, offered with their praxis. If their successors have retreated into the world of auto-poetic self-engagement, action researchers are called to think more broadly about the dimensions of time, practice and voice in our praxis. Where conventional social scientists focus only on controlled studies about the past (time), action researchers also usefully consider a future (e.g. what future are we contributing to?). We might also ask, for example, whether and how people’s aspirations for creating a future together influence their practice. And where conventional social scientists focus on third parties (voice), action research needs to consider our own personal reflections on action (first person work) along with the reflections of those we regard as co-researchers (second person work). All efforts result in insight useful to co-ordinating mutually agreeable action. Indeed it is because of its multidimensional character that action research can help explain more of the empirical variance in situations than conventional science.

The multiple dimensions of quality are primarily concerned with promoting the good of a social system, as understood and enacted by the stakeholders in that system. Because what is ‘good’ is rarely a straightforward matter, reflection is required among those involved as to what is learned and who is served. Thus, useful responses to a challenge, combined with reflection on what are the shared conditions that make something useful, constitute the basic building blocks of creating quality action research.

Choice Points for Quality

All knowledge is political in the sense that as *shapers of discourse* we have political agency in our efforts. This applies also, or especially, to the shaping of discourse on what constitutes quality. The following seven criteria offer a useful and tested starting point on what constitutes ‘quality in action research’. They are the product of an ongoing ‘collogue’ among action researchers associated with the journal *Action Research*.

1. *Quality requires articulation of objectives:* Quality is reflected in the extent to which the action research explicitly addresses the objectives relevant to the work and the choices made in meeting them.

2. *Quality requires partnership and participation:* Quality is reflected in the extent to and means by which the action research reflects or enacts participative values and concern for the relational component of research. By the extent of participation, we are referring to a continuum from consultation with stakeholders to stakeholders as full co-researchers.

3. *Quality requires contribution to action research theory-practice:* Quality is reflected in the extent to which the action research builds on (creates explicit links with) or contributes to a wider body of practice knowledge and/or theory, which contributes to the action research literature.

4. *Quality requires appropriate methods and process:* Quality is reflected in the extent to which the action research process and related methods are clearly articulated and illustrated. ‘Showing’ and not just ‘telling’ about the process and outcomes usually means including the voices of the participants in the research.

5. *Quality requires actionability:* Quality is reflected in the extent to which the action research provides new ideas that guide action in response to need.

6. *Quality requires reflexivity:* Quality is reflected in the extent to which self-location as a change agent is acknowledged for how it both enables and limits knowledge creation. By self-location, we mean that action researchers take a personal, involved and self-critical stance, as reflected in clarity about their role in the action research process, clarity about the context in which the research takes place and clarity about what led to their involvement in this action research.

7. *Quality requires significance:* Quality is reflected in the extent to which the insights are significant in content and process. By significant, we mean having

meaning and relevance beyond their immediate context in support of the flourishing of persons, communities and the wider ecology.

Approaching Quality as Choice Points

It is simply not possible to have all quality measures to be of equal importance throughout all phases of all action research. Judicious choices must be made. The key point is that quality requires that these choices be made transparent. Where important, concern for conventional validity may be included inside a broader spectrum of quality choice points. This is particularly important, for example, when writing an action research dissertation as dissertation committees often look for conventional forms of rigour. Making choiceful decisions is the result then both of art and of systematic inquiry, with action researchers integrating what is most appropriate to the setting.

Action researchers may well help with revitalizing the practice of social science with the spirit of partnership. The lack of priority given to the specifically relational and pragmatic nature of human living and knowledge creation has led to blind spots and dead ends with conventional social science. Davydd Greenwood has documented the growing crisis of irrelevance that limits the impact of conventional social science, unmitigated by increasing calls to develop what is variously called translational or implementation science. The latter comes as an afterthought to the continued use of conventional methods, which discount the fundamentally relational, pragmatic reality of social inquiry in the first place. The gap between theory and practice cannot be effectively addressed through epistemological argument and translational afterthought but can be understood in terms of building research practices as social capital. Action researchers design for relational, pragmatic action from the start. More partnerships between action researchers and conventional social scientists would appear promising.

For action research, with its integration of pragmatic and relational subjectivity as a central feature, replication and generalizability are therefore also reimagined. In reality, there is little that is independent—all phenomena co-arise and are interdependent with one another. Action researchers are therefore called to investigate and work also at expanding the boundaries of their work. Here, quality as partnership and participation is to be taken seriously by including a view outwards, which requires scouting the external boundaries of a project while our view is naturally drawn inwards to the local stakeholders. Social networks and global networks, supported by social media, can only bode well for this interdependent future work.

The Future of Quality: Stretching Towards Inclusivity

Implications of a Relational World View

A relational-pragmatic world view, and the ethic and practice of partnering that arise from it, has far-reaching political implications when we consider partnering with those heretofore omitted from the research. For example, in health-care action research, the ethic of partnering means including patients as key stakeholders in decisions that affect them. In education, it means including students. In business, this means looking beyond financial stakeholders to social and environmental stakeholders. Each of these efforts to stretch towards inclusion of heretofore excluded stakeholders goes against strong cultural norms and power positions. It is precisely in this practice of partnering that we see the emancipatory potential of action research that guides the practical and technical outcomes in the work with stakeholders.

Action researchers are attuned to the importance of relationships and relational networks. It is noteworthy that, to a degree, action research still labours with an essentialist view of the self which sits awkwardly with the relational practices. Turning again, with Habermas, to the American pragmatists, such as Dewey and James with their relational understanding of the thorough-going interdependent rather than separate self, may be the beginning also of a more relational conceptualization of the self for action researchers. Freed from an anachronistic, mechanistic world view, a thorough-going relational understanding of the self frees us from believing that we ought to be doing research in accord with the dictates of conventional validity (as a bounded individual developing my theory) and leads us to doing work informed by the needs of stakeholders. This, in turn, better situates action researchers to take the next step in garnering more support for our way of doing work—namely, by developing relationships across large networks of practitioners/scholar-practitioners (perhaps aided by the globe-spanning social media), bringing a stronger focus on building relationships inside our research and also within the action research community itself.

The integration of reflexivity in contemporary action research, which means stretching to include the inner landscape of the self, may well be the most significant contribution action research makes to social science more generally. The reflexive self is largely omitted from objectivist research. Action researchers are, relative to conventional social scientists, more autobiographical in expression because we acknowledge that all claims to knowledge are shaped by interests since knowledge claims are never neutral. An author's reflexivity helps contextualize the claims, create transparency and anchor ownership of expression, which can otherwise masquerade as worryingly disembodied and neutral. We might say

that reflexivity is as much a part of explaining any project as is the array of methodological and literature review statements at the outset of most conventional articles.

For example, Erica Foldy offers her reflection on how White racial identity shaped and, in turn, was shaped by her dissertation data collection. She identifies specific choices and experiences in the research interviews that were influenced by race, using both data from her own journal as well as feedback about the interviews from two informants of colour. She traces how conducting the interviews and writing about them make meaning of her own racial identity. She offers these reflections as a contribution to two conversations, both related to exploring and learning about race. First, her discussion of how being White influenced her study contributes to important dialogues about how researcher identities reverberate through the research process. Second, her consideration of the change in her own racial identity suggests implications for those interested in learning from and about race. In turn, the European-American Collaborative Challenging Whiteness were invited to respond to her published reflections. They wrote in support of Foldy's premise that we cannot learn about race until we make it a 'discussable', thereby joining her in reflecting on the relationship between her White identity and her dissertation research. They conclude by describing an important state of inquiring mind that they call critical humility. In this work, we see the potential increase in rigour brought about by including first person perspectives. The turn inwards is as important as the turn outwards.

Debra Merkin's research with primates, *Hearing Voices: The Promise of Participatory Action Research for Animals*, pushes the limits out beyond the familiar 'humans-only' boundary normally used to determine who constitutes a research subject. The implications for all our work are thought-provoking. Merkin seeks to articulate an action research approach that fully accounts for those who are silent, most especially in inter-species studies. We are confronted with the ubiquity of the ideology of superiority that insists upon a strict boundary between human and other than human. We may yet come to know the universe as composed of subjects to be communed with rather than of objects to be exploited. Such radical studies may yet come to represent a formal turning point for action research, and for social science more generally, in expanding how we define research subjects as participants. This means that we must consider more clearly what relationship and participation may mean.

Conclusion

Quality in action research is multidimensional, leading to choice points for developing quality. Concern for partnership and participation refers to the quality of the

relationships with primary stakeholders and the extent to which all stakeholders are appropriately involved in the design and assessment of inquiry and change. Concern for actionability refers to the extent to which the work provides new ideas that guide action in response to need, as well as concern with developing action research crafts of practice on their own terms. Reflexivity refers to the extent to which the self is acknowledged as an instrument of change among change agents and stakeholders. Significance means having meaning and relevance beyond the immediate context in support of the flourishing of persons, communities and the wider ecology. Stretching further outwards, inwards and towards deeper inclusivity in the work of action research may well be the new horizon in nurturing the future quality of action research.

QUANTITATIVE METHODS

Quantitative methodology is the dominant research framework in the social sciences. It refers to a set of strategies, techniques and assumptions used to study psychological, social and economic processes through the exploration of numeric patterns. Quantitative research gathers a range of numeric data. Some of the numeric data is intrinsically quantitative (e.g. personal income), while in other cases the numeric structure is

imposed (e.g. ‘On a scale from 1 to 10, how depressed did you feel last week?’). The collection of quantitative information allows researchers to conduct simple to extremely sophisticated statistical analyses that aggregate the data (e.g. averages, percentages), show relationships among the data (e.g. ‘Students with lower grade point averages tend to score lower on a depression scale’) or compare across aggregated data (e.g. the USA has a higher gross domestic product than Spain). Quantitative research includes methodologies such as questionnaires, structured observations or experiments and stands in contrast to qualitative research. Qualitative research involves the collection and analysis of narratives and/or open-ended observations through methodologies such as interviews, focus groups or ethnographies.

Quantitative approaches to research can be very powerful and useful to social scientists. For example, they provide researchers the ability to systematically compare responses across many people in a relatively inexpensive, fast and consistent way. Some methods, like surveys, can provide a space for people to share personal information in an anonymous way that they would otherwise be unwilling to share with an interviewer. And politically, quantitative research can open doors to audiences who privilege numeric results. However, Participatory Action Research (PAR) is more often known for its use of qualitative rather than quantitative methodologies. This is not a coincidence. The collaborative and engaged approach of PAR tends to overlap more naturally with the flexible, open-ended, thematic approach of qualitative research. However, PAR reflects a commitment to democratic participation and social action more than a commitment to any single research method. Therefore, PAR researchers should not avoid projects that are best served by quantitative methodologies. Indeed, quantitative approaches do create a set of challenges that PAR researchers must find creative ways to contend with. This entry first reviews some of the challenges to the use of quantitative research methods in PAR and then provides examples of studies in which quantitative methods have been effectively used in the context of PAR projects.

The Challenges of Quantitative Methodology for PAR

Quantitative Bias and ‘Real’ Science

In the social sciences, there is a bias towards quantitative research as ‘real’ science. While potentially informative, quantitative tools convey a sense of authority and persuasiveness. The appearance of precision and the illusion of neutrality can make them seem somehow above critique. However, counting is

a fundamentally exclusionary human activity. To count is to make a choice about what is included and what is excluded: not only what to count and how to count but who to count. Thus, quantitative research can both distort and enlighten, has strengths and weaknesses and should be in conversation with, not in opposition to, qualitative methods. Quantitative methods or analyses are sociopolitical practices that are historically and contextually situated. Researchers employing quantitative approaches are not without bias when making decisions about what should be researched, what questions to ask, how the data is interpreted and what should be presented.

For PAR researchers to effectively conduct quantitative research, they often find it important to take a critical stance. A critical perspective on quantitative methods and statistical analyses does not only (or even largely) suggest critique, but instead it also invokes a commitment to historical connectedness, political awareness, an intersectional standpoint, methodological heterogeneity, redistribution of expertise and public and community involvement. A critical approach to quantitative research involves using numbers in a principled way towards the larger pursuit of democratic participation and, in service of marginalized communities, to reveal oppressive systems, institutions and policies. A critical approach to quantitative research is connected with theories that help understand social inequality and help promote activism, emancipation and justice.

The Rigid Assumptions of Statistical Inference

The data produced from quantitative research is analyzed using statistical techniques. Courses that teach statistical analyses devote most of the time to reviewing inferential approaches. Inferential statistics are designed to use sampled data in order to estimate (infer or generalize to) information regarding the population of interest. This is done using statistical probability and the collection of data through probability samples (e.g. random or randomized samples). Inferential statistics tend to be deductive and hypothesis driven, with heavy guidance from predetermined theories. At its most conservative, all of the analyses are pre-planned so as to not capitalize on chance or random fluctuations (i.e. Type I error, family-wise error). Quantitative research using inferential statistics involves a set of very restrictive assumptions and requirements that can produce an inflexible environment that runs counter to the intent of PAR.

Many prominent statisticians have cautioned the social sciences regarding their over-reliance on complex modelling and unwarranted causal claims. The general concern is that the complexity of social and

psychological experience is often uneasily or inadequately captured through quantitative means. The proposed remedies often involve a more humble stance on the limits of quantification, a more varied use of research methodologies, greater reliance on replication and greater willingness to explore one's data. In addressing this last point, a set of statistical techniques called exploratory data analysis (EDA) is particularly useful to PAR researchers since it stands in contrast to the rigidity of inferential statistics.

EDA is an iterative, descriptive, graphical approach to statistics. Its techniques are designed to probe for possible patterns among the individual responses in the sample, rather than using the data to statistically generalize to a larger population. While it is always important to consider sampling, EDA does not necessarily rely upon probability (and probability sampling), and therefore frees researchers to investigate what the data reveals without fitting the findings within a formal, rigid structure—similar to analyzing interview transcripts. For example, a series of quantitative participatory techniques called stats-n-action is rooted in collaborative EDA. One part of this technique engages in a back-and-forth process, with the research group thinking through what quantitative relationships would be interesting to test, immediately running those analyses using a projector to display the results and then using the output to mediate a deeper conversation about what they think it means and what further slices of the data need to be examined to make the best interpretations. Thus, EDA provides an open-ended approach, stressing description and flexibility, that often does a better job at fitting the goals of PAR than the more traditional quantitative approaches.

Disconnected Research Moments and Isolated Expertise

Quantitative research, when used appropriately and under the right circumstances, has a lot to offer in the way of data collection and analysis. Yet, the quantitative piece, particularly the statistical analyses, is often seen as disconnected from the rest of the research. It can too often serve as a gatekeeper to participation, separating the expert from the layperson. The necessary critical conversations that numbers should facilitate are disconnected and reserved for 'professionals'. The person with statistical expertise is assigned the power to report back 'what was found', and for those on the research team who are anxious about numbers, this quantitative process can serve as an alienating conversation closer. Thus, statistical information produced from quantitative methods can too often be un-jointed and un-participatory, shutting down critical discussion and therefore not conducive to the commitments of PAR.

When examined closely, the quantitative research process is actually a series of highly connected, small and large decisions with multiple opportunities for broad and interactive participation (e.g. the strategies for measurement, the questions that are asked, the sampling, how the data is 'cleaned' in a data set, how the variables are disaggregated and aggregated, how and with whom the analyses are discussed). Therefore, quantitative PAR researchers have found creative ways to promote statistical literacy and critical, democratic participation throughout the quantitative process by demystifying the technical complexity of quantification and allowing for opportunities to collaboratively run, interpret and trouble simplistic quantitative interpretations of human experience. A movement called 'Barefoot Statisticians' embodies this participatory ethic and creativity. Barefoot statisticians are trained to serve the local community's basic quantitative needs for the purposes of critical democratic engagement and activism in the spirit of China's 'Barefoot Doctors', who are locally trained to provide the basic medical and health needs of poor and rural communities.

Two Examples of Quantitative PAR

The next section will provide brief overviews of two quantitative PAR projects that have effectively combined participation with numbers to uncover great empirical insight with strong social action.

Morris Justice Project

The self-report survey, also known as a questionnaire, is probably the quantitative method most commonly used by participatory action researchers. The work of the Morris Justice Project is within the historical lineage of 'community self-surveys' and the mid-nineteenth-century to early-twentieth-century amateur and localized quantitative efforts that became known as the Social Survey Movement. These multi-methods studies (e.g. community surveys, mapping, interviews) tended to be explicitly conducted for the purposes of social justice, reform or human rights. Usually with the help of local volunteers and grass-roots organizations, extensive data on many layers of social and economic factors is collected within a relatively defined community.

The Morris Justice Project was designed to document the experiences of living in a heavily policed neighbourhood. From 2011 to 2013, researchers collaborated with and sampled from a single, 40-block community in the South Bronx, which had the highest percentage of police contact leading to physical force in New York City. The research team was composed of elders, mothers, fathers, youth, students, university faculty from the City University of New York, researchers

at the Public Science Project and public interest attorneys from Pace University Law School. This team of co-researchers developed all of the research questions, methods, analyses and products collaboratively.

The participatory design began by making connections with local community members in order to build a research team interested in studying experiences with and attitudes towards the New York Police Department. Over multiple sessions and rich discussion in the local public library, the research team developed a survey as well as interview questions. Surveys were distributed systematically block by block and filled out in person using a pen and clipboards. Surveys were also distributed with the help of local businesses, churches, the library and social networks. Over 1,000 surveys were collected. Additionally, the research team conducted focus groups and individual interviews.

The research team analyzed the quantitative and qualitative data collaboratively. The findings were used towards a broad set of local and citywide activism intended to raise awareness as well as support ongoing legal and legislative work. This included producing a local newspaper series to communicate the experiences/impact of aggressive policing, co-sponsoring events with community organizations to address neighbourhood safety and producing an active social media campaign in solidarity with court cases and legislation related to police reform. In addition, and throughout the research process, the lawyers on the research team provided education and legal services for individuals living in the neighbourhood.

Child Friendly Cities and Communities Research Initiative

The Child Friendly Cities and Communities Assessment and Monitoring Project was an international evaluation focused around a series of deeply democratic and participatory community surveys. In 1996, UNICEF and UN-Habitat created Child Friendly Cities to ensure that urban spaces were liveable for children and their families. The programme was intended to foster the human rights of children and youth by adopting participatory governance and urban management approaches. Hundreds of cities globally have since labelled themselves 'child friendly'. While progress at the national policy levels was successful, contextually relevant community input in developing and implementing this initiative was limited, particularly from children. Furthermore, there were no tools for assessing and monitoring how 'friendly' the child environments were.

Thus, researchers and practitioners at UNICEF Innocenti Research Centre, Childwatch International and the Children's Environments Research Group of

the City University of New York developed community surveys measuring a set of common child-friendly indicators (e.g. play and leisure, safety and protection, educational resources). They were designed to be collaborative, educational, locally flexible, richly informative and used on/by/for/with a broad group of community members, including children, adults as well as community providers and authorities. In addition to documenting conditions, the participatory surveys were designed to promote awareness of child rights and serve to voice grounded concerns to policymakers, urban planners and local governance. The surveys have or currently are being used in many cities across nine countries: Brazil, the Philippines, Dominican Republic, Morocco, Jordan, Sudan, France, Italy and Spain.

The community surveys involved participatory activities engaging children, parents and local service providers in the data collection, analysis and interpretation of the data. The surveys incorporated words and pictures for every item and scale (e.g. never true, sometimes true, mostly true) in order to enable comprehension by children. The data collection or analysis process involved group participation through the use of poster-size surveys and colourful stickers, which the participants used to indicate their answers. Such active engagement and visual display of data allowed for immediate critical reflection on collective numeric tallies across items, including the evaluation of bivariate patterns (e.g. gender and age differences). The process also facilitated democratic discussion of how the overall frequencies and averages exposed needs for improved living conditions, application of rights, new community programmes, more inclusive policies and stronger governance structures that support the quality of child-friendly urban conditions.

Conclusion

Quantitative methods play a dominant role in the social sciences; however, they can pose challenges to PAR researchers, whose epistemological, ontological and ethical commitments can stand in contrast to traditional quantitative approaches grounded in a positivist world view. As a result, merging quantitative and participatory strategies requires creative awareness of the numerous opportunities for collaboration that exist throughout the quantitative process. When done well, quantitative participatory research has great empirical power to advance our knowledge and inform our actions.

R

REFLECTIVE PRACTICE

The most common general meaning given to reflective practice is that it involves thinking about what one has done after completing an activity or while one is still engaged in an activity. The usual purpose of this is to improve what one does, to develop and grow, or to find new ways of thinking or doing. Reflective practice is often thought of in concert with the idea of continuous learning. While not exclusively so, reflective practice is usually taken to be something that people engaged in professional practice might and should do. While reflective practice might occur at an unconscious level, outside of our awareness, most of the discussion about it concerns how to make it deliberate. In fact, identifying processes that might assist people to become effective reflective practitioners is a concern of a large body of literature. This entry initially examines the origins, definitions and various perspectives people have about reflective practice. It then goes on to look at what has been said about the relationship between action research and reflective practice.

Definitions

Desiderius Erasmus (1469–1536) once stated that ‘reflection is a flower of the mind, giving out wholesome fragrance; but revelry is the same flower, when rank and running to seed’. The important message from Erasmus seems to be that reflection involves effort, design and purpose by being something more than idle thought. Indeed, dictionary definitions of reflection generally refer to the cognitive activity of reflection as careful thought or consideration. However, this definition does not quite capture the meaning applied to reflection by academics, educationalists and practitioners engaged in using reflection in practice. For example, Dewey defined reflective thinking as a number of phases involving a state of doubt, hesitation and mental difficulty. This results in action that will resolve the incongruity.

David Boud and his colleagues have described reflection as a process involving both emotion and cognition that results in a new understanding of a phenomenon. Don Schön, like John Dewey, saw reflective practice as thoughtful consideration of one’s previous experience while connecting theory to practice. While reflection can be a quite unconscious process without purpose, most practitioners who use the term *reflective practice* take it to be a deliberate activity that has a method and can be taught. It is often thought as a continuous activity and, in some cases, a response to critical incidents that occur in one’s life or work.

Some, however, take reflection to be somewhat more than changing what one does and include examining the deeper aspects of oneself, such as motivation, emotional response, values and beliefs. The reflective process involved in Buddhism is an obvious case in point, although this understanding of reflection is seen in more secular activities such as education, psychology and sociology. In this conceptualization, reflection is sometimes perhaps confused with the notion of reflexivity, which involves the process of examining cause-and-effect relationships. In particular, reflexivity, as it applies to the social sciences, concerns self-referent behaviour arising out of action. Reflection is commonly and inappropriately taken to mean the same as reflexivity.

Reflective practice takes on a slightly different meaning from reflection alone. There are a number of interpretations of what reflective practice entails that will be explored in the next section. But a generic definition is that it involves practitioners using processes to examine their performance and increase personal awareness so that they create opportunities for growth and development.

Perspectives on Reflective Practice

The idea of reflection can be found in the work of the ancient philosophers. Reflection for Confucius (551–479 BC) was seen as the most noble of ways to learn wisdom. Socrates is well known for his quite

famous reflection that ‘the unexamined life isn’t worth living, behind every experience there is room for interpretation of the meaning of that experience’. Indeed, the Socratic method involving the use of artful questioning of another’s viewpoint is a form of active reflection. Marcus Aurelius was probably engaged in reflective practice in his *Meditations*. The Buddhist literature is replete with references to reflection, particularly of the self, through meditation. Certainly, reflection needs to involve higher level cognitive activity. John Biggs muses that when one looks in the mirror one just gets back what one sees. Clearly, reflection needs to be more than that and should involve an improvement in what one does.

More recently than Confucius and Socrates, and with more direct reference to practice, John Dewey is perhaps the best known modern author to canvass the idea of reflection in his writings about education and the teacher. For Dewey, thinking could be either deep, and hence meaningful, leading to positive future action, or ‘idle’, where experience just passes through the mind. Dewey thought that reflection is the process that enables meaningful thought. He considered reflection to be critical to the ability to test one’s beliefs and assumptions against data and other possible interpretations in a scientific and systematic way. Thus, reflection is more than an idle occupation or meditation and is deliberative in nature.

In a broader sense, Dewey thought that this process was essential in a democracy and, hence, critical in education. Thus, it is not sufficient to just be involved in an event, an intellectual bystander; it is important to be able to make sense of it. To this end, Dewey thought that either education could enhance this ability and lead to intelligent action and be positive or it could retard growth and be negative. There are two principles to positive reflective thinking. The first of these is continuity. This is an assumption that one’s experience will affect one’s future, either positively or negatively. The second principle is interaction, which is the active comparison of present experience with past experience.

There are five main elements to Dewey’s concept of reflective activity:

1. Suggestion making that involves coming to rapid initial solutions.
2. A conscious cognitive recognition of the complexity that the person has experienced with respect to the problem that is being solved.
3. The serial use of each suggestion as a hypothesis to guide further collection of facts.
4. The intellectual elaboration of the hypotheses or suppositions.
5. Testing the hypothesis by intentional action.

These elements have been criticized because they seem to have a linear rather than dynamic quality, as if it is a method to be followed. In addition, there is no real concern with dialogue other than that which is internal to oneself. Others suggest that the role of emotion, such as doubt, needs to be included in any attempt to provide a model.

An interesting aspect of Dewey’s notion of reflection is that people who are able to practise reflection have certain characteristics that these days would be seen as personality attributes. These characteristics are open-mindedness, responsibility and wholeheartedness. These are components of what are now known as the Big Five Personality Traits, which have been shown to predict behaviour.

Inspired by Dewey and Lewin, David Kolb incorporated the idea of reflection into his Experiential Learning Model. The model consists of four parts: (1) concrete experience, (2) reflection on the experience, (3) theorizing from the reflection and then (4) testing the theory. Perhaps the most well-known and greatest contributor to the notion of reflective practice, and the originator of the term, is Don Schön. Like Dewey, Schön thought that a key element of reflection is the capacity to draw on past experience that for the expert practitioner is intuitive.

This intuitive decision-making occurs at the moment one is doing something. Perhaps, the person is confronted with a problem, or something is not going well. There may be an instant insight that there is a better way to do something, an improvement. Schön called this reflective process, ‘reflection-in-action’ that occurs spontaneously during an event.

Closely related to reflection-in-action is the concept of ‘knowing-in-action’, which was derived from Michael Polanyi’s notion of tacit knowledge. Usually found in the repertoire of the expert practitioner, tacit knowledge becomes obvious only during the carrying out of a task or while solving a problem, and perhaps not even then. The problem or task is often complex and expertly done. However, articulating tacit knowledge is no easy task, requiring a high level of self-awareness.

Schön also identified a different reflective process, which he called ‘reflection-on-action’. As the name implies, this occurs after the event and is mostly a more conscious process of examining what happened. This reflection might be planned, a structured process and a part of what has more recently been called continuous improvement. In addition, Schön thought that it could occur in a quiet moment when the person starts thinking about the event. This might be stimulated by a sudden awareness that something isn’t quite right or that in fact the whole experience went very well, and the mind starts to wonder why. Reflection-on-action

can occur with another person, Socratic perhaps, or in a group, or it might involve writing things down. This latter process has proved to be very popular in recent times and, as we shall see later, is commonly used in action research as a reflective diary.

An extension of reflection-on-action is the notion of double-loop learning, which was described by Schön. Compared with single-loop learning, which is a reflection on what happened, double-loop learning involves examining underlying assumptions or what Schön called 'theories-in-use'.

These processes were central to Schön's belief that practitioners can be taught how to reflect more effectively. This can occur during the Reflective Practicum, in which learners are coached by expert practitioners who demonstrate reflection-in-action. Then, a formal process is used to teach how to do reflection-on-action so that it becomes part of the practitioner's repertoire. For Schön, reflection is not just one-dimensional but a 'ladder of reflection'. In a Socratic process, the learner and the teacher can reflect on the activity, they can experiment to test assumptions and, ultimately, they can reflect on the process of reflection.

Schön thought that in order to learn and to understand, one had to enter into an experience without any attempt to prejudge. Borrowing from Coleridge, he called this the 'willing suspension of disbelief'. At the same time, there is a need to attend and absorb information and to participate in the experience rather than simply observe. Schön called this process 'operative attention'.

Applications

Reflective practice has been closely associated with the idea of lifelong learning and professional development. But it has mostly been embraced as fundamental to professional practice and professional identity. There is considerable reference to the application of reflective practice in the educational literature in particular, closely followed by nursing. Other professions, such as sport coaching, management coaching, medicine, management and consulting, for example, have also adopted reflective practice as a professional activity. Most of these applications of reflective practice have tended to take a retrospective approach rather than reflection-in-action.

In nursing, the model most often used for reflective practice is Graham Gibbs' Reflective Cycle, which was derived from Kolb's Experiential Learning Model, mentioned previously in this entry. Gibbs suggests reflection as providing an analysis of the situation and describing what happened, what thoughts and feelings were involved, what was good and bad about the experience, what could have been done differently and what would be done differently the next time. Many

practitioners will recognize similarities between Gibbs' model and Reg Revans' description of Action Learning. This consists of asking questions after an event, as follows: What was planned? What actually happened? What worked? What didn't work? What would we do differently next time?

For some, this process doesn't go deep enough. Real change is thought to come from the more introspective activity that questions values and beliefs, our schema about the world. It is here that the notions of reflexivity and reflective practice become blurred. David Boud and his colleagues, in the field of education, have come close to combining the two with their three-stage model. This involves reflecting on the experience by replaying it in their mind in a descriptive and non-judgemental way, examining feelings and discharging those that are negative and then re-evaluating the experience in a new way. This latter stage consists of association (comparing new information with current knowledge), integration (making new relationships among and between data), validation and appropriation (making the new understanding one's own).

Another model used in the health field, largely with nurses, is Johns' Structured Reflection. This, as the name implies, is a very structured approach to reflection (i.e. a virtual checklist) and has the advantage of providing a framework for teaching reflective practice.

The idea of reflective practice seems intuitively sensible, and to a large extent, its advantages are self-evident. However, this has led some commentators to reflect that there is not much in the way of evidence to support it as an activity, outside of the anecdotal. More important, there have been warnings that reflection can be poorly executed, leading to erroneous conclusions. Others even suggest that reflective practice, particularly of the more introspective kind, can be harmful to how people see themselves and, ultimately, have an emotional impact.

This is a somewhat sobering thought and supports the conclusion that there is a need for more systematic research about the effectiveness of processes that purport to develop reflective practice, the impact on people and whether or not reflective practice in fact produces any real outcomes.

Reflective Practice and Action Research

There have been arguments put, mainly by the educational community, that reflective practice often occurs without any framework or structured methodology to guide it. Action research provides such a structured framework, in which reflection is an integral part. It provides a link between action and theorizing, and reflection. At the same time, action research uses methods such as journaling, memoing, recording,

storytelling and autobiographies, for example, as vehicles for undertaking reflection. The often collaborative nature of action research enhances the potential for critical reflection, usually in relation to practice.

Kurt Lewin was one of the early pioneers to discuss the merits of reflection as a scientific endeavour within the context of action research, which he first mentions in 1944. Reflection is a component of the action research spiral that is discussed in great detail throughout this encyclopedia. Within Lewin's conceptualization of action research, reflection is a purposeful, conscious activity: part of a problem-solving activity. Thus, Lewin linked thinking with action. Lewin was also interested in bringing about social change, the betterment of society, through action research, of which reflection on data and action was a part rather than an end in itself.

It was later, through the work of educationalists such as Lawrence Stenhouse and John Elliott, that action research was applied to the improvement of the practice of teachers, which could be either an individual or a group activity. In these models, the teacher is seen as a researcher on her own practice, and reflection is tied to the research process. For Elliott, action is initiated by reflection but needs to end in action. Following contemplation of the identified problem, the teacher then might try out a variety of solutions and see what happens, modifying the approach on the way. In what has been coined as *educational action research*, reflection takes a central role and is seen as a professional quality that needs to be learned by teachers.

For Richard Winter, reflection is not given the precedence it deserves in conceptualizations of action research. He argues that reflection is the core activity that enables us to make sense of the world, of the evidence that we have gathered. However, he goes further to invoke the notion of reflexivity, which is required to try and explain phenomena. Reflection then is informed by reflexivity on process and theory.

Reflective practice and action research are both cyclical and concerned with improvement and creating the opportunity for change. They are both emergent with action dependent on an evaluation of what has been learned from reflection. Schön saw action research and reflection-in-action as equivalent. However, there are times when action research legitimately involves reflection-on-action as either an individual or, more often, a group activity. Elliott also sees reflective practice and action research as the one and the same.

The exact nature of both action research and reflective practice are, according to some, still relatively vague and still needing more robust conceptualization. Whether they are the same activity is also open for discussion.

REGIONAL DEVELOPMENT

The notion of 'region' may span from a 10,000 square-mile territory in the Arctic with a handful of inhabitants to 'the region of Asia'. For the notion of 'region' to acquire meaning, it is necessary to link it to specific discourses. For action research, there are, in particular, two perspectives that have been important: one emanating from internal differences within nation states and one from the need to introduce several levels of organization to build the bridge between local developments and broader waves of change.

Differences between units that live under the same general conditions have for a long time attracted interest in social and economic research. The interest in regional perspectives emerging in recent decades can, however, to a large extent, be brought back to Italy and to the differences between the North and the South. Against the stagnant South, there is a North characterized by affluence, modern business and administration; a high rate of innovation and a leading-edge position internationally within areas like design, fashion and sophisticated industrial products. How can these differences exist side by side?

There are many possible explanations, from history and culture to technical skills. Widening the perspective to include differences within other countries as well, much of the attention has come to focus on knowledge and, in particular, the notion of surplus knowledge. With new knowledge continuously available, enterprises can continuously renew their products,

services and processes and, consequently, develop and grow. New enterprises will more easily be created, and enterprises from other places will move in because there are knowledge resources available for exploitation. Over time, the result will be affluence and the ability to finance more knowledge creation and strengthen the spiral. In many versions, this is the basic assumption behind the notion of the knowledge-driven economy.

Why should the search for exploitable knowledge lead to regional organization? Many enterprises are too small to directly benefit from global sources and are in need of local mediators, such as local universities or other gatekeepers. With a growing emphasis on experience-based knowledge, there emerges a need for social mechanisms that can transfer this kind of knowledge between enterprises, with an ensuing demand for direct contacts. The use of knowledge is not only a question of identifying relevant sources, it is also a question of the reliability of the sources. This leads to the issue of trust, an issue that has gained prime importance in the innovation context. The generation of most forms of trust will benefit from direct contact. In sum, a common vision today of an 'innovative environment' is an area where a number of enterprises can be found, in association with institutions of higher learning, with providers of risk capital and with public authorities intent on promoting innovation, all linked to each other in the form of various arenas for co-operation. Otherwise, they vary from, say, Silicon Valley, with several million inhabitants, to regions with maybe a hundred thousand. There is no sharp boundary between region and other social collectivities, such as community.

With its orientation towards how to make knowledge actionable, and towards the social processes needed to link actors to each other, action research is a natural candidate for an important role in this kind of knowledge-driven development. This demands, however, that action research be able to fill a role within contexts that are sufficiently broad and complex to defend the notion of region. Historically, action research is strongly linked to the dynamics of face-to-face groups, units rather far from regions. This leads to the other discourse that has brought the issue of regional development to the forefront in action research: the discourse on how to transcend face-to-face contexts to create more broadly framed processes of change. Several approaches have been tested in this context, and the one that has proven fruitful is the use of regional links and ties; a pioneering example is the Baldwin Corridor project in Pennsylvania.

Even in relatively small regions, research cannot reach all people directly. What is important is to reach all interest groups and types of actors: not only political leaders or the management of large enterprises but

also unions, ordinary employees, small enterprises, public services, educational institutions and whatever other types of actors may be important. If it is possible to reach all major types of actors and link them to each other, these actors can generally exert a pull on a wider range of actors, making it possible for action research to relate to fairly large regions. Those who represent the different types of actors are there in their capacity as representatives, not leaders. Although there may be an element of leadership development in the process, this is to take place in a collective form through the creation of the mutual trust that makes it possible for many people to govern together rather than through building up the capacity of a few actors to direct the rest.

Reaching out in this way can sometimes be done in one sweeping move, through large-scale interventions, that is, mass meetings. Such events covering whole regions are, however, very difficult to organize. The common procedure is to build the links and relationships stepwise. Core measures in this context are various forms of encounters where actors are brought together and given the opportunity to find out if they want to work together and in what way. Encounters of this kind often lead to spin-offs in terms of project groups and other units for the performance of specific tasks or to follow-up events of various kinds. In most cases of action research involvement in regional development, action research is responsible for organizing and facilitating the encounters and, in this context, for deciding what encounters to organize and in what sequence. In constructing an innovative region, it is important to work from a long-term perspective where all actors of potential relevance are not only pulled in but also used at a time and in a way that is consistent with the roles of the different actors. In the Grenland region in Norway, a group of process enterprises discussing work organization were the first participants successively to be joined by their local suppliers, by institutions in research and education and, when this alliance had become sufficiently strong to exercise a major regional pull, by the regional political authorities. The discussion agenda, which started with work organization, today includes many forms of competence development and innovation support. From being a 'rusty region', Grenland now appears as a dynamic one with a high score on innovation and with more people employed than ever before.

Regions like Grenland and the Baldwin Corridor are characterized by much of the innovations emerging out of the learning of the established actors in the region, such as workers and managers in the enterprises that are already there. Even when innovation is linked more strongly to scientific advances—even global spearhead advances—a regional organization is quite common—Silicon Valley again being an example. Even though

the notion of 'region' constitutes a common ground, the more specific strategies needed to create and sustain the region as a framework for innovation will differ. The type of system the process aims to achieve will influence what challenges appear and what should be done about them. Are all employees in all organizations to be mobilized early in the process? Are there local research institutions that are to be partners? What encounters are called for to link the various elements to each other? What events are particularly well suited to create the mutual trust called for in a pattern of horizontal co-ordination? In the thinking about how to construct 'the ripples in the water' effects needed to create a regional framework for innovation, two notions appear as particularly important: (1) the notion of innovation system and (2) the notion of social movement. With roots in economic theory, contributions under the heading of innovation systems tend to emphasize structural characteristics, sharply featured lines of reasoning and a traditional perception of theory; social movement tends, with roots in social sciences such as anthropology and sociology, to emphasize the organic, the interactive and the openness of the process. Insofar as action research has entered the field of regional development, the contributions tend to fall more under the social movement perspective than under the innovation system one.

Regional processes generally involve many different types of actors and organizations and are often made up of a number of different but overlapping part processes. To understand where we are each and every time and what the next step should be is often difficult. This has provided research with a major function beside the creation of the links: to keep track of what happens and to interpret events. These research contributions often form the point of departure for what encounters are organized and what agendas are set. This does not necessarily imply that research provides a lengthy summing up before the encounter gets going. In most cases, it is the actors concerned who tell the story; where research can help is in pointing out which actors should be called upon.

The notion of region is, today, popular within a number of politically defined areas. The European Community has divided Europe into regions, and national bodies often build administrative systems on a regional perspective. Common to most of these orders is that the regions tend to be much larger than those that action research has, so far, been able to handle. While many of the regional architects in politics and administration move top-down and create 'quasi-states', action research needs to move bottom-up and, consequently, always needs an anchoring in concrete realities. What is to be seen as a region cannot span beyond what can be anchored in the lifeworlds of its inhabitants.

While the notion of region, at least in 'the West', has been strongly linked to strategies for employment, growth and innovation, there appears a widening of the perspective, in three directions. First, in the wake of the finance crisis, more weight is placed on the issue of socially responsible innovation. Since social responsibility can be created only through surrounding the innovation process with a democratic dialogue among the people concerned, the region appears as a possible framework. A second factor is the growing interest in social innovation. Social innovation not only demands but also is generally identical to changes in the relationships between people, and such changes need to be pioneered within frameworks that allow for concrete forms of collaboration and joint learning, pointing the region out as one of the important frameworks. Third, while the efforts to provide help in the development of Third World local projects often seem to be successful, the efforts to transform states into open and democratic institutions have fared less well. This implies a need to strengthen the bottom-up processes, pointing out the region as a major area for future efforts.

RELATIONAL-CULTURAL THEORY

Relational-Cultural Theory (RCT) posits that we grow through and towards relationships throughout the lifespan. This model, which originally grew from a feminist base and was aimed at altering traditional models of human development and clinical practice, has been expanded to better understand the power of connection in all people's lives. RCT rejects a view of human development as a path towards separation, independence and safety achieved through exercising power over others. The need for connection is

seen as essential to human life from beginning to end. In healthy relationships, mutual empathy, trust and responsiveness prevail, forming the basis for social justice and new, more equitable power arrangements. Built on clinical observation and research in psychology, RCT advocates a major theoretical shift based on a new paradigm that applies relational-cultural models to wide and fundamental social change.

Core RCT Concepts

The core ideas of RCT point to the centrality of relationship in people's lives. Initially developed to better understand and represent women's experience, RCT now posits that all people grow through and towards connection throughout the lifespan. RCT also studies how highly individualistic cultures interfere with growth-in-connection and undermine psychological well-being. 'Power-over' systems combined with hyper-individualistic, competitive values create chronic and destructive disconnections as well as unhappiness for people who feel pressured to separate and go it alone. RCT has not only contributed to the practice of a more relational and contextually sensitive therapy but also stressed the importance of social change and social justice to bring about more mutuality and connection in all our lives. Practising the RCT precepts of mutual empathy, authenticity, 'power with' and growth-in-connection challenges the hyper-individualistic status quo in psychology, psychotherapy and social political organization.

Until quite recently, most Western developmental and clinical theories were built around the notion of 'the separate self'. Studies show that the USA has placed far more value on developing a separate self than any other society. The dominant ideals of those in power—White, male, middle-class, heterosexual males—lead people to believe that acting out of self-interest and finding safety in exercising power over others is the best and most natural way to be in the world. Standards of maturity and psychological well-being are often skewed in the direction of building a strong separate self. Thus, child rearing, clinical interventions and educational policy have all focused on the importance of bringing dependent babies into an adult state of independence, autonomy and self-sufficiency.

'Hardwired' to Connect

New neuroscience data supports the core concept of RCT that humans grow through and towards connection throughout the lifespan. Humans need connection as much as they need water and air; they are neurologically hardwired to respond with extreme urgency to isolation or exclusion. People's brains function best and grow in relationships; the pain of exclusion travels

to the same area in the brain (the anterior cingulate) and is recorded in the same way as physical pain. Functional MRI (magnetic resonance imaging) studies show us that social pain is *real* pain. This has implications for social programmes and attitudes towards groups that are marginalized and excluded from the mainstream. The pain of exclusion and even the threat of exclusion are as debilitating for people as serious physical pain, such as that from chronic arthritis, migraines or severe burns. Isolation is one of the essential sources of suffering in people's lives. Our bodies and brains are primed to register extreme alarm when we are cut-off from human connection.

Rethinking 'Human Nature'

Influential developmental theories and popular culture have contributed to a misrepresentation of human nature as basically greedy, selfish, aggressive and initially lacking in the capacity to care about others. According to this model, people need taming by a vigilant and controlling society, and children have to be socialized to control their primitive antisocial natures and to be kind. Darwin's concept of the survival of the fittest is misrepresented as a testament to the success of raw, self-interested and aggressive competition, even though Darwin gave ample credit to the importance of co-operation and collaboration to individual and group survival. Researchers now know that one of the core contributors to ecological adaptation is the capacity for flexibility and resilience, which depend heavily on relational factors. Neuroscience data and RCT point to the importance of building mutual and empathic relationships and good vagal tone. Misrepresentation of self-interest as a biological imperative that defines human beings, rather than a social prescription, is a distortion of our core relational nature and allows the slanting of social policy in a pessimistic direction.

RCT argues that mutuality should replace the dichotomy of selfishness versus selflessness, the prevailing model characterized either by competition over scarce resources (me first, greed, zero sum) or self-sacrifice. In mutual relationships, people contribute to each other's growth, to the relationship, and then move towards increased trust, appropriate vulnerability and openness to being affected by one another. Safety is gained by building good connections and not by exercising dominance over others.

Working With Disconnections and Building Resilience

In the RCT model, people are seen as growing in connection and suffering in isolation. Acute disconnections—such as thoughtlessness, misunderstanding, ignoring

people and empathically failing one another—are inevitable in any relationship, but they can be reworked so as to build stronger and more flexible connections. If a person with power hurts a person with less power and the less powerful person can represent his or her hurt to the more powerful person, who then responds with empathy and earnestness, both people develop an enhanced sense of mattering to each other and of being effective. Trust grows, and the relationship gains strength, stability and resilience. If, however, the more powerful person disregards the less powerful person's feelings, fails to express interest or concern or responds punitively, it can lead to chronic disconnection. For instance, the less powerful, hurt person begins to feel that she has to hide both her sense of hurt and her self-protective or angry response. As an adaptive survival strategy, the injured person gradually keeps more and more aspects of herself out of connection in a particular relationship, building relational images that prohibit certain expressions. These particular relational images become overgeneralized so that the person feels that her anger is not acceptable in any relationship. As she brings less and less of her authentic experience into other, possibly all, relationships, the liveliness and zest generated in a growth-fostering relationship begin to disappear. People begin to lose their sense of worth and clarity and become less productive and more isolated from others. Jean Baker Miller coined the term *five good things* to describe the outcome of growth-fostering relationships: (1) an increased sense of zest, (2) greater clarity, (3) a sense of worth, (4) increasing productivity and creativity and (5) a desire for more connection. Chronic disconnections lead to the opposite, draining individuals, relationships and communities of vitality, stability and creativity.

Healing Through Mutual Empathy

Mutual empathy is at the core of healing in RCT. For empathy to provide a healing experience, the client must be able to see, hear and know that she has had an impact on the therapist. She must know that she *matters* in this relationship and will be responded to in a way that puts her interests at the core of the interaction. Much healing takes place around reworking relational failures and working with relational authenticity on the part of the therapist. When the therapist misunderstands or empathically 'misses' where the client is, it is important that the client sees that the therapist notices and regrets the misreading or the hurt he or she has inflicted. The therapist is responsive, not reactive. The therapist's role is to protect the well-being of the client by carefully providing feedback that helps the client see the impact she has on others. In this way, the client develops increasing relational competence and

feels less alone. Clients whose early-life relationships led them to feel that their feelings, thoughts, reactions and pain do not matter can be heard and respected in the therapeutic relationship. Their needs and hopes can be responded to, and disconnections can be reworked. Mutual empathy points to the fact that relationships which foster growth for one person are growth fostering for both people.

By nature, people are drawn towards mutual engagement, which involves profound respect and openness to being moved, touched and changed by each other.

When Culture and Psychobiology Clash

Culture is not an add-on in RCT but is seen as central to the way people grow, thrive or face daunting hurdles. Cultures shape values, meaning systems, what gets defined as good, strong, successful or shameful. In cultures that idealize separation and autonomy, people may feel invalidated and shamed if they experience a sense of need or dependence. Given that most human beings inevitably feel vulnerable, uncertain and dependent in various ways, this sets people up for a sense of failure. The disconnection and clash between cultural prescriptions and neurobiological realities create stress and an enormous dilemma for all people living in hyper-individualistic cultures. When we are pitted against our own neurobiological inclinations by cultural prescriptions and imperatives, great stress is inflicted on our bodies and our brains. The brain, however, is characterized by enormous neuroplasticity. Growth-fostering relationships can rebalance and reshape brain structure and functioning throughout the lifespan. In fact, empathic connection is a prime source of positive brain growth and change. Our capacity for empathy grows when we exist in a world that is characterized by empathic responsiveness. An empathic relationship is likely one of the core sources of healing and growth, both in psychotherapy and in everyday experience.

Mutual Empathy and Action Research

Mutual empathy is not simply a 'feel-good' mood elevator for individuals but rather a basis for social justice. Radical respect for others' experiences, openness to being moved and influenced by others and shared power are at the heart of social justice. Societies that empathically attend to the needs of their more vulnerable members are societies that are good for everyone. Data now shows that when empathy levels fall in a society, violence increases, economic inequality increases, instability infiltrates the social institutions, health conditions worsen and educational systems are short-changed. Anxiety, depression and a

sense of powerlessness ensue when economic inequality is rampant. Individual well-being and communal stability suffer under conditions of low empathy and significant economic inequality. Action research in the RCT model is about applying the understanding gained through theory building, clinical insights and neuroscience research to changing the social arrangements that threaten our individual health and global sustainability.

RELIABILITY

Reliability in research is the quality of consistency in a measure or procedure. This entry begins with a brief definition, then moves on to an exploration of the applications of the concept of reliability in quantitative research and consideration of its applicability to action research. The entry explains that when action research includes quantitative measures, conventional views of reliability can apply to that part of the research. Conventional means of attaining and affirming reliability can be used. In other action research, the applicability

of the concept is disputed. Those who argue for its use may advocate an alternative or a less stringent concept of reliability. Methods from some of the qualitative research literature may be relevant. Even in more emergent forms of action research, some of the strategies used to achieve reliability elsewhere may still be useful. Finally, not all consistency is useful. The entry concludes with a consideration of ways of achieving useful consistency that take into account the special nature of action research.

Definitions of Reliability

Reliability is a concept derived from quantitative research. There, a reliable measure is one that yields consistent results. It may be described as consistent or repeatable. Reliability is often contrasted with validity. A valid measure is one that measures what it claims to. An example often given is that a reliable clock, in the technical sense of the term, is one that is consistent, even if always fast or slow by a fixed amount. On the other hand, a clock is akin to an adequately valid measure when it always very nearly indicates the correct time, even if sometimes a little fast or a little slow. Together, reliability and validity provide accuracy. A measure that is very unreliable cannot be valid. Reliability without validity is not useful.

Yvonna Lincoln has proposed the use of the terms *dependability* and *consistency* in qualitative research as replacements for *reliability*. In some literature, including some action research literature, this has become common usage. Lincoln has since advanced *stability* as a more appropriate term, less indebted to positivist notions of good research. In consequence, there is no commonly agreed-on terminology for the concept in qualitative research.

Reliability can also be applied to procedures or processes, where it is the characteristic of being repeatable. A reliable research procedure delivers the same result on the same sample at different times or on different but equivalent samples. In their much cited monograph, Jerome Kirk and Marc Miller call these 'diachronic reliability' and 'synchronic reliability', respectively. For procedures or measures, reliability is often reported as a correlation coefficient or sometimes as the percentage of agreement between the results being compared.

Quantitative Measures in Action Research

Although most action research is qualitative, quantitative measures may be incorporated as part of an action research study. This is not unusual, for example, in some community-based participatory research. A team consisting of researchers and community members may

administer quantitative measures perhaps to determine what the focus of the action research is to be or for diagnostic purposes. The administration of the measure and the collection and scoring of data follow quantitative research protocols. Researchers and research participants then determine collaboratively the local relevance of the scores and their practical implications.

For such quantitative components, traditional definitions of reliability apply. High reliability is achieved by adopting the practices of good quantitative research. This is likely to include strategies such as standardized administration, judicious random sampling and careful recording of results.

Questions About the Applicability of Reliability

There are features of most action research that impair reliability as conventionally conceptualized. The necessary flexibility of a process that is intended to produce action also generates unpredictability. Each turn of the action research cycle typically has an action component, usually intended to change the research situation. There are therefore ongoing changes to the research setting in which the action research takes place. The participatory nature desirably leads to diverse views, with the result that outcomes change from time to time and are therefore initially unpredictable. The collaborative nature of participation can lead to apparent consistency that in reality is a false consensus (see the discussion below).

Attention to reliability as a concept is not strong in the action research literature, even in work that does consider validity. Some authors have dismissed it on the grounds that traditional views of reliability assume an unchanging world. For reasons discussed above, action research is very likely to face a changing and less predictable situation. Where research standards are discussed in such literature, terms such as *rigour* and *quality* are more likely to be used.

It is relevant that for some decades there has been a debate, sometimes vigorous, about the status of action research as scientific research. There are academic journals and academic departments in which only traditional experimental approaches to research are accorded high status. Different authors respond to the dispute in different ways. As action research consists of a large family of research approaches, attitudes vary. Action researchers also subscribe to a variety of philosophical positions.

Some researchers use forms of action research that are able to meet many of the requirements of traditional research. Also, to achieve funding and publication, authors may adopt traditional research criteria. This is true of some educational action research, for example,

which at times resembles quasi-experimentation. In such forms of research, reliability and validity are achievable if their definitions are relaxed compared with those in traditional use.

Research quality is a theme given more attention in action research since the late 1990s. For instance, it features prominently in both the 2001 and the 2008 editions of the *SAGE Handbook of Action Research*. There is also a growing literature in both action research and qualitative research generally that encourages the achievement of research quality by means other than those common in quantitative research. In qualitative research, Lincoln has been an advocate for alternative approaches, favouring terms such as *consistency* and *dependability*—or, more recently, *stability*—as replacements for *reliability*.

Practices for Improving Reliability

Matthew Miles and Michael Huberman have proposed what amounts to a checklist for reliability. It takes the form of a number of questions a researcher can ask. Some of these questions are likely to fit only a limited range of action research studies. For instance, they assume that data is first collected and only then coded. This is less common in action research than in most other research approaches. As a further important example, they (and others) recommend standardized procedures for collecting and interpreting information. However, in most forms of action research, the research process as well as the information is improved from cycle to cycle. The saying attributed to Kurt Lewin that to understand a system you try to change it captures this characteristic well.

Other Miles and Huberman criteria may be useful, especially in the less empowering forms where the researcher maintains a distinct role from the other participants. For example, they recommend questions about issues such as clarity of the research questions and the use of research features that suit the questions; an explicit role and status for the researcher; parallel findings from different sources of data; the use of appropriate samples of settings, times and informants; ways of maintaining comparability of different researchers' work and so on.

The maintenance of adequate documentation as the research proceeds can provide the audit trail that some authors recommend. This may take the form of the field notes common in much qualitative research. In more participatory and empowering varieties of action research, it may consist of notes taken on whiteboard or chart paper as the discussion develops.

Some of the Miles and Huberman criteria are applicable whatever the form of action research used. For instance, they suggest attention to the convergence or

otherwise in different observers' account and some form of peer review.

There are also forms of reliability that actually undermine validity. Information may seem reliable because there is consistency across researchers and across sources of information. Sometimes, this consistency arises in ways that actually acts against the validity and usefulness of the information. For example, it may be consistent because there is a conventional but inaccurate view held by participants. It may be often expressed. If it is never confronted by disagreement or by contrary evidence, it becomes a norm. Or the consistency may arise because participants have guessed at the purpose of the research and are being co-operative by giving what they perceive as the right or the expected answer. Kirk and Miller call this false consistency 'quixotic reliability'. Fortunately, ways of dealing with it can be applied in most forms of action research and much other qualitative research too. Some strategies for doing so are described in the next section.

Approaches to Reliability in Action Research

As mentioned, there are features that militate against the achievement of reliability—and perhaps cast its relevance in doubt. However, whether termed reliability or something else, random inconsistency is not desirable. Importantly (and fortunately), the very features of action research that threaten to inhibit reliability can instead be used as sources of research quality.

For example, the involvement of participants as co-researchers has the potential to provide varied and rich information. If a culture of honest collaboration is created, the resulting synergy can yield high-quality interpretations. This is more easily done in very small groups or in one-to-one interviews (see the entry 'Convergent Interviewing'), though even here, it is not a trivial matter. As Chris Argyris has maintained over many decades, it is rarely achieved. It requires both trusting relationships and a willingness to discuss topics that may not be easily discussable. Argyris has also given reasons why all or most social research faces this issue. With its commitment to empowering relationships, action research is better placed than much social research.

When direct and open relationships are achieved, heterogeneous participants can generate diverse viewpoints. In resolving their different perceptions and opinions, participants have the opportunity to develop a deeper understanding of the situation they face and how it might be improved. This is most likely to be achieved when any initial inconsistency is resolved through meaningful discussion. In a process analogous to Louise Kidder's negative case analysis, participants can provide information disconfirming of

others' views. The disconfirmation can have the effect of refining the growing collective understanding. The early stages of an action research study are therefore very important in establishing a suitable culture and appropriate participant roles and expectations.

The action orientation of action research, together with its cyclic process, is potentially a further advantage. The wish for beneficial change provides a common goal to be pursued. In addition, participants realize that their emerging understanding will face a reality check when they attempt to convert their understanding into action. This occurs in each action research cycle.

In summary, the relevance of the concept of reliability to action research is not a resolved issue. Whether or not reliability applies to action research, there are practices that can remove undesirable randomness from information. When this is done, finding agreement within diverse perceptions, and transforming that agreement into action, is a worthwhile endeavour.

RESEARCH CIRCLES

Research circles (RC) as they have developed over the past decades in Sweden constitute a Participatory Action Research (PAR) device that particularly emphasizes the participatory and collaborative dimensions of this tradition. They were launched in the mid-1970s in Sweden as an answer to radical changes in society at that time. In these circles, a group of people, gathered because of a mutual problem, meet in order to establish a basis for action by further exploring the issue. The work in the circle is strengthened by the participation of one or more university researchers, who are responsible for the mutual knowledge work. Generally, RCs are intended to be a kind of knowledge bridge between the more experientially flavoured knowledge of ordinary people and the academic or theoretical knowledge carried out in universities. They constitute a tool for collective and democratic knowledge work and thus contribute to breaking the divide between the researchers and the researched.

Procedures

In an RC, about 5–10 people work together in order to enlarge and deepen the knowledge about a mutual problem. An agreement to meet regularly is needed, generally at least 5–10 meetings for 2–3 hours at a time. Most of the RCs will go on much longer, and it is not unusual that they last for years, sometimes changing their focus in response to new challenges. In an RC, the participants have access to an abundance of knowledge resources. The practitioners contribute with their first-hand knowledge about the focus problem. The researchers bring to the circle their knowledge from research that has relevance for the problem. They also contribute with their professional competence as researchers in dealing systematically with research problems, developing new knowledge and documenting the process. Further, they have the function as members of the academic community to find colleagues from various disciplines who can contribute to the circle work with relevant research. In this way, potentially all research in any field from any corner of the world could be accessible for the RC. Not least important, the researcher can bring the fundamental scientific attitude of being critical and at the same time be self-critical in the sense of being humble, open to new perspectives and willing to modify his or her own knowledge.

Characteristics

The mutuality in the creation of knowledge is characteristic of what is going on within an RC. The knowledge

transmission that takes place between the participants is not directed either from above or outside. Since the members of the group together own the problem, it is the right and the duty for everyone to contribute in the collective knowledge building. The role of the participating researchers is not using their academic knowledge to exert power over the content or direction of the circle work. On the contrary, it is their task to take into consideration and to value all kinds of knowledge and experience. At the same time, it is also important that researchers can critically challenge all kinds of knowledge, not least research results. By doing so, RCs can be described as examples of democratic knowledge processes where the knowledge construction is taking place in co-operation with all concerned and where different interests are considered.

The researcher who is trained to work in order to create new knowledge has the duty to facilitate the process. In order to ensure that the experiences and perspectives of everyone are made visible, he or she needs to be a good catalyst. It is a responsibility to bring forward the hidden knowledge, the experiences from individuals as well as structural perspectives. The researcher has a duty to bring to the circle other research that is done about the problem under scrutiny. It is also essential that the participants can discuss and question their findings together. In this way, democratic knowledge processes also contribute to a better knowledge base from which to act in order to change the participants' circumstances. The results can be manifold, and what is achieved is always documented by the participating researcher.

There is a great potential knowledge concerning the breadth and depth of the problem under scrutiny that already is at hand within the participants (the researchers included) of the circle. And there are many opportunities to gather more knowledge through researching activities by the circle or by bringing knowledge from a variety of research to the circle. The fact that sometimes very different kinds of knowledge are simultaneously accepted as relevant and regarded with a critical distance is also enriching.

History

Study circles are well known in Sweden, and most Swedes even have personal experience of participating in a study circle. They have roots in the nineteenth century and were important for educating the developing labour movement during the beginning of the twentieth century. Nowadays, there are several study organizations providing circles in a variety of subjects, often like small evening courses. But it is still possible for a group of people to organize a study circle around their own topic.

The concept 'research circle' was coined in Lund in Sweden in connection with a pilot scheme with university courses for trade union representatives, with content related to the newly passed labour laws (e.g. the Co-Determination Act of 1976 and the Work Environment Act of 1977). Together with these courses, the unions organized study circles as a kind of support for their participants. It was observed that both university teachers and union representatives were curious and eager to share in each other's knowledge and experience. A simpler arrangement for this mutual exchange was sought, and so the idea to revitalize and extend the study circle into an RC was born.

In the beginning, RCs were initiated by trade unions around various topics like work environment, municipal and regional development, or union organizing. Researchers at the University of Lund from a number of academic disciplines were engaged, and the work of the circles was documented and reported. Soon, the RC idea spread around Sweden, inspiring not only unions and their members but also various groups of people and organizations to start circles. Today, for example, RCs are used in the school and education system, in health care and eldercare, with immigrants and handicapped people and so on. The RC idea has also been tried in other countries in Europe and in South America and South Africa with varying success.

There have been many ways of providing the economic conditions for the work in RCs. During the 1980s and 1990s, trade unions in Sweden had the labour laws and a Work Environment Fund to support representatives and union members in participating in circles. Even for researchers, there existed several funding opportunities to pay for their work in RCs. In the neo-liberal era, these advantageous conditions have become rare, and in the 2010s, there exist comparatively few union-initiated RCs. Today, circles have been organized in a number of ways, for example, as parts of research projects, as part of education or as elements of development projects.

Different Kinds of RCs

It is apparent that the RC is a very flexible tool for knowledge work that can be adapted to many different contexts and uses. The original flavour of the RC idea is connected with the ambition to contribute to strengthening groups of people and social movements wanting to 'change the world' in a genuinely humanistic and democratic spirit. But like action research in general, there are many differing approaches and ways to use this tool. A rough classification of RCs that could be made is as follows:

1. *Emancipating circles* dealing with empowering people: Many of the first circles were of this kind. Some of them were with working-class women, for example, cleaners, factory workers and nurse assistants. The early circles often had a historical perspective, including groups such as farmworkers, typographers and butchers.
2. *Strategic circles* dealing with comprehensive social issues: Circles of this kind could involve trade unionists and politicians who wanted to deepen, understand and create tools to achieve a better impact on issues such as the European Union, the privatization of the common sector and the role of trade unions. It has also been used in working to support gender equality and other issues of general importance in schools and communities.
3. *Pragmatic circles* dealing with organizational or professional issues: In these circles, the focus has been on issues like work organization, school development and work content in different professional branches.

Potential Advantages

From the perspective of the university, RCs can contribute to developing the university into a so-called Mode-2 university more open to the society and interacting more with parties outside the academy. This might improve the university's social status by establishing the idea of the university as a useful knowledge source in the public mind. In Sweden, it is regulated in university law that universities should 'collaborate with the surrounding society', and consequently, the use of RCs is one way of doing just this.

From the researcher's perspective, RCs have the potential of giving access to knowledge that is difficult to obtain through traditional research. First, the knowledge and experience of the circle participants is of great potential value for the researcher. Sometimes, life history approaches or interviews can be used to tap this knowledge source. Second, the participants might also provide access to research in their context, for example, their workplace, organization or company. Another potential gain for the researcher is the opportunity to get feedback on research results or perspectives presented to the circle. Not least important is the fact that the researcher often gets inspiration from the work of the circle to initiate further research.

The participants in the circle deepen their knowledge about the problem that has been the focus of the circle. A very common observation is that participation in an RC is empowering for the participants to varying degrees. Their self-confidence usually increases; they

acquire new knowledge and feel more competent in putting forward their demands.

In relation to the PAR tradition, it seems clear that RCs are inherently participative, they prepare for, inspire or include action and provide an excellent arena for merging research and experiential knowledge and for doing research together.

Potential Drawbacks

First, the idea—like all good and constructive ideas—could be misused. Its positive side of being flexible in a good sense unfortunately also has a negative side of being too easily adapted and thereby losing the original potential as a democratic and an emancipating tool. There is a risk that it might even be used to enhance opposite interests that have a hidden and manipulative agenda.

Second, conditions are not always optimal or even suitable for RCs. They seem to demand at least a minimal level of preparedness for this idea concerning democratic knowledge work on the part of both the universities and the organizations or groups in society. In Sweden, the idea has been (and still is) compatible with some existing traditions, like the study circle tradition, providing scope for this kind of activity, and the same holds for other parts of the world where similar democratic traditions exist.

Finally, RCs are time-consuming, usually going on for at least half a year and often much longer. This means that resources in the shape of time and economy for the participants and their circle work must be found. These resources are sometimes not easily obtained.

Despite the aforementioned challenges, however, RCs are recommended as a promising and useful device for PAR.

RESEARCH INITIATIVES, BANGLADESH

Research Initiatives, Bangladesh (RIB), a not-for-profit organization, was founded to promote knowledge on poverty alleviation that is relevant, useful, innovative, participatory and action oriented, with a special focus on marginalized and socially excluded communities. RIB views poverty as a multidimensional process and recognizes that the needs of poverty groups go beyond simple income generation, food and shelter to areas such as equality, dignity, justice, human rights and good governance. RIB supports marginalized and minority groups who are unable to access basic services due to social discrimination and conducts people's research (*gonogobeshona*) on the development schemes that affect them most, in order to develop ownership and generate community mobilization.

Over the years, RIB has conducted and implemented over 200 action-based research and follow-up development projects among 31 'missing communities'—that is, communities whose agendas are not addressed by mainstream organizations. RIB has also undertaken action research-based development activities among the seasonally food-insecure and drought-affected mainstream marginalized farmers and wage labour households of northern Bangladesh through dissemination of appropriate agricultural technologies. During the past 10 years, RIB has reached, through its Research Partnership Network, around 20,000–25,000 socially excluded and marginalized households. During this period, through its Kajoli preschool programme, 5,000 children from 1,200 economically ultra-poor households are entering primary schools annually with full preparation. It has also trained and developed around 1,100 community-based internal animators or facilitators to undertake and help poverty reduction among the rural marginalized communities.

Currently, RIB is implementing (a) a project to promote the implementation of Right to Information Act, which is supported by Rosa Luxemburg Foundation for the third phase; (b) dissemination of Kajoli Early Childhood Learning Centres (a model developed through research within RIB) for the children of marginalized families, supported by Kwintet AB of Sweden; (c) conducting of preschool programmes through community mobilization for the children inside the refugee camps of Cox's Bazar as the implementing

partner of United Nations High Commissioner for Refugees; (d) dissemination of agricultural technologies for improving food security and adaptation against drought and flash floods among the marginalized and landless households in Nilphamari district under the CSISA-IRRI-RIB (CSISA, Cereal Systems Initiative for South Asia; IRRI, International Rice Research Institute) Partnership project and (e) strengthening of the indigenous Santal community's rights to land, government services and education as a partner of NETZ Bangladesh, a German non-governmental organization funded by the Ministry of Foreign Affairs, Germany.

The following are some of the characteristics of RIB's approach to research.

First, RIB believes that Bangladesh's research agenda should be based on local needs and perception. However, a truly demand-driven approach should consider the demands of the people themselves, the intended beneficiaries of the research, to be the main basis for identification of research topics.

Second, the research projects that RIB supported over the years have been largely based on application of the participatory research approach. RIB's efforts were aimed at ensuring that people benefiting from the research should be involved in a continuous process of inquiry. It has been seen that when peoples' views are treated with respect, they are eager to participate in the search for knowledge on their own situation rather willingly. It boosts their self-esteem and enhances their confidence.

The participatory approach was taken a step further through the application of the internationally acclaimed Participatory Action Research (PAR) approach, which became a hallmark of RIB's work. The PAR approach has demonstrated that when ordinary people are involved in a research process aimed at improving the conditions of their lives, they begin to reflect on those conditions and initiate change. The efficacy of PAR, which is based on the principle of reflection, followed by action, followed by reflection again, has been amply demonstrated in many RIB-supported research projects. As a result of RIB's efforts in promoting the approach, PAR has acquired a new name in Bangladesh. It is now popularly known throughout the country as *gonogobeshona*, or 'peoples' research'. Since action is a core element in such research, the results are easier to follow up at the policy or advocacy level than conventional research.

Third, RIB began its work on the premise that poverty is a multidimensional and dynamic process and not simply an experience of economic deprivation. It includes considerations of knowledge and skills, human resources and capacities, vulnerabilities and coping strategies, gender inequalities and human security and finally social exclusion and people's initiatives. Using these indicators, one can effectively

develop a perspective on poverty alleviation from the point of view of the most deprived groups and minorities in Bangladesh, whose needs have thus far not been addressed by the development establishment, government or non-governmental.

Fourth, by identifying social discrimination and ethno-racialism as a cause of poverty in its work, RIB has sought to include these factors as being equally responsible for the under-development of minority communities as well as the hampered growth of a secular and democratic polity. Forms of social discrimination such as untouchability and caste consciousness have kept many downtrodden communities, such as the *kewras* ('pig rearers'), *rishis* ('leather workers') and *horijons* ('sweepers'), on the margins of development. Ethnic discrimination against indigenous people by the majority community has kept many in these communities from accessing social justice and the benefits of developmental activities. For these communities, therefore, achieving self-dignity forms an equal part of their development agenda as food and shelter. The development needs of such communities therefore traverse the realms of needs and rights. PAR, such as the ones the RIB focuses on, has served as an apt tool for community and development workers to reach out to the needs of these 'missing communities'.

Fifth, due to scarcity of academic or professional researchers to undertake research on poverty issues, RIB had to turn to capacity building of new, young researchers to fill the gap almost from the beginning. RIB's efforts in this regard were aimed primarily at people who may not have the necessary academic background for research but who are more attuned to the ground situation and committed to participatory research. Over the years, through many workshops in and around the country and through short-term project support, a large number of young men and women have been equipped to serve as researchers and/or research animators.

RIGOUR

Positivist scientific inquiry aspires to imbue knowledge production with rigour that enables the objective replication or falsification of the results. The knowledge produced by such rigour in science is deemed by other scientists to be trustworthy. Action research more often responds to a different paradigm of inquiry, variously labelled qualitative, naturalistic, interpretivist, post-positivist and so on. Consequently, action researchers often hold on to general principles of qualitative rigour, such as those detailed by Yvonna Lincoln and Egon Guba. Because such studies involve unique social contexts, they cannot be repeated with exactitude, which means that rigour cannot be demonstrated through repeatability. Since it is not possible to replicate action research studies, rigour in the action research paradigms must enable the post hoc assessment of the results' truth-value through applicability, consistency and neutrality. In such paradigms, the rigour of the research process makes the knowledge products trustworthy because researchers are demonstrably shown to be engaged and aware of the context, open and attentive, careful and conscientious, sensitive and empathetic and honest and reflexive.

Qualities of Action Research Rigour

The rigour in an action research study provides the means by which knowledge outcomes attain four important qualities of trustworthiness. These qualities are credibility, transferability, dependability and confirmability. For each of these qualities, there are features in action research studies that provide the opportunity for researchers to instil the rigour that ensures the trustworthiness of their results.

Credibility

Credibility requires convincing evidence of the integrity of the research and the plausibility of both the process and the results. Rigour in action research can achieve credibility in unique ways. One way involves a sufficient time commitment to enable a demonstration of how the results of the actions taken achieved a

solution that assuaged the practical problem at hand. Such demonstrations might be qualitative or quantitative, but there should be convincing evidence that an enduring problem solution arose from the study. In action research, these achievements often occur after multiple iterations of an action research cycle have both rejected unproductive theories and established useful ones that precipitate valuable results. Action research can draw rigour from the achievement of a useful outcome that is demonstrably relevant to the action undertaken. Because action research results are actionable, the success of the action is one possible confirmation of the results. However, because action research engagements are sometimes situated in complex social contexts, they can become prolonged until such a demonstrably relevant solution becomes evident.

Credibility also arises when the research rigorously tracks the consequences of actions in terms of the problem under examination and the theory underlying the formulation of the action. Such a focus on the relevance of the theory-action-consequence relationship in each of the study iterations adds rigour in terms of the persistent observations that are required to cover both practical and theoretical outcomes.

Credibility is further enhanced by the iterative nature of most action research methods and the rich sources of data that become available when researchers intervene in social settings. Interview data is useful, but there are also meeting notes, log files, memoranda, e-mail, participant journals and so on. Such rich and varied data sources arise because actors in the setting (often both researchers and subjects) are usually deeply engaged in determining serious actions and interventions in the research setting. Further, multiple iterations of action research can involve changing or adapting the theory base for determining action. These data sources and expressed theories are replicated in each of the iterations of the study. Iterations build a large volume of empirical data in the study. More important, this research database provides a potential means for triangulation on the findings from multiple data sources, multiple theories and multiple iterations in which theories are applied to determine actions in the setting. Triangulation as an element of action research rigour means that multiple sources of data, multiple iterations of method and multiple theories all point to the findings that embody the knowledge produced in the research.

Credibility also arises because reflexive evaluation is often a key process in action research methods. Many action research methods involve a distinct evaluation activity that includes appraising the outcome of the actions and specifying what has been learned about the setting, theory, action and so on. Careful conduct and

documentation of evaluation processes provide several opportunities to instil rigour into the research process. For example, where a collaborative team is engaged, a carefully documented team debriefing as an evaluation component provides negative case analyses of what did not work, what undesirable outcomes resulted and why these negative results might have arisen. These evaluations can rigorously document the theory-action-consequence relationships. Once the research achieves its final action outcome, the evaluations will not only provide an analysis of the final iterations but also return to earlier, unsuccessful iterations to examine and possibly explain failed theories and actions. Such comprehensive evaluation provides the rigour of referential adequacy (the ability to explain the outcomes in previous iteration events from the theoretical perspective of the final, established theory).

Transferability

Transferability requires sufficient knowledge about action research theories, actions and results to enable other researchers to use the knowledge in future. The rigour in achieving credibility provides the basic groundwork for transferability. However, in action research, transferability means that further use of the knowledge must account for the unique features of the setting in which the study was conducted. For transferability, future researchers must know enough to decide whether the results from a past action research study are relevant in a novel setting. In action research, both the theory and the action may be conditioned by the exact social situation. The research results must provide sufficient documentation of the social setting to enable someone to compare it with a future social setting in order to appraise the differences and potentially adjust the action, or even the theory, for a novel setting. Applying action research knowledge requires an understanding of both the original setting and the novel setting. Action research methods sometimes employ ethnographic data collection techniques to enable transferability. These techniques include thick descriptions, confessional diaries and structured journals. Action research methods provide particularly strong opportunities to increase their rigour through transferability. This rigour is enhanced because actions taken without careful consideration for the social setting will often fail to achieve fully the desired outcomes. The opportunity for research rigour arises because evaluation involves explicit learning about the interaction of the theory and the setting.

Dependability

Dependability requires that the knowledge offered in an action research study will operate successfully

in the future. Like an experiment, an action research study will usually be able to show that its theory and its action are known to work only once. A rigorous action research study will include features that indicate that its knowledge will be dependable in the future; it should operate more than just once. Action research studies achieve dependability through the iterative cycles present in most action research methods. Near the end of such studies, confidence in an operating theory will build as minor successes lead to major ones. Final iterations will often expand actions from limited experiments to broader operating solutions. Dependability is achieved by rigorously iterating action research studies until the theory-action-consequence moves beyond an action experiment to become a documented operating solution.

Confirmability

Confirmability requires that an action research process can be reconstructed, even if it cannot be repeated. A rigorous study will yield sufficient documentation to support an independent audit of the action research process. Few action research studies may be subjected to such inquiry audits, but rigour is achieved when the documentation is present and available for such an audit. Such an inquiry audit can operate from a carefully administered research documentation database, necessary to achieve credibility, transferability and confirmability. In qualitative methods, such as action research, the purpose of an inquiry audit is to confirm the knowledge from not necessarily the research but rather the process by which the knowledge arose. Action research is a highly situated process, and an inquiry auditor may lack an adequate background in the exact social setting to confirm the content of research decisions. However, the inquiry auditor can review the procedures and the data to confirm that the research was conducted properly. The researchers' own journals are perhaps the most important element in the research database for the purpose of confirmability. When the researcher journal is reflexive, it provides a primary means for an inquiry auditor to distinguish and appraise the care with which both the objective and the subjective contributions were made by the researchers to the actions and the consequences of the study.

Assessing Rigour and Its Value

For scientific journals, the qualities that define research rigour also provide one source of criteria for determining whether a research report should be published. Peer reviewers will often try to assess whether studies have rigorous features. Reviewers focus on the credibility aspects that should be evident in reports.

Examples of the questions such assessment may drive include the following: Did the action research achieve the desired practical outcome (prolonged engagement, dependability)? Is the theory linked to action and its consequences in each of the iterations of the cycle (persistent observations)? Was the data carefully collected, in each of the iterations, from the subjects and the researchers involved (triangulation)? Were the failed actions closely examined (negative cases, referential adequacy)?

Scientific rigour is sometimes contrasted with the relevance of scientific studies, and action research may be seen as one solution to this contradiction. Strongly scientific studies can be so reductionist that the results are nearly meaningless for a practical expert with a real problem to solve. Because experimental models reduce social settings to a few testable constructs, practising professionals struggle to apply the results in rich social settings. Action research proponents argue that it is possible to use action research, with strong methods and tightly maintained links between theory and practice, to engage real settings with rigorous research features that lead to both scientific and practical knowledge. Rigour and relevance, however, do not guarantee breakthrough social science discoveries. Action research studies sometimes can only rigorously

confirm that well-known theories operate correctly to solve difficult problems in novel settings.

S

SCHÖN, DONALD

Donald Schön was an iconic thought leader and practitioner of action research. His multifaceted and multi-layered inquiry into the nature of everyday practice led to key concepts that have helped shape action research and organizational intervention; the nature of professional knowledge and know-how; the process of technical, business and social innovation and professional education. Over a span of nearly 40 years he worked as a manager, a management consultant, the leader of a consulting firm and professor and department head, while continuing to explore the nature of practice and publishing books with great regularity.

Schön's legacy includes the identification of key processes such as (a) the use of the 'generative metaphor' in making sense of new and difficult situations; (b) 'beyond the stable state', describing the state of impermanence of organizations in a changing environment and the challenge to their 'learning systems'; (c) 'espoused theory' and 'theory-in-use', capturing the gap between what professionals and organizations say they do and what they actually do, based on observation and inquiry, and using that gap as a catalyst for change (with Chris Argyris); (d) 'single-loop learning' and 'double-loop learning', describing learning in practice within a constant frame and learning that reshapes the frame that informs individual and organizational action (also with Argyris); (e) 'the artistic component' of professional knowledge, ignored in instrumental views of knowledge; (f) 'rigour versus relevance', to capture the dilemma of practitioners who want to go beyond the circumscribed problems and canons of professional practice; (g) 'experimentation on the spot', to capture how highly skilled professionals address difficult problems that defy their current understanding, leading to new knowhow and knowledge, and (h) 'frame-reflective discourse', capturing the process that shapes how opposing views, values, perspectives (frames) and

interests can come to resolution of intractable social problems (with Martin Rein).

Career

Schön was born on 19 September 1930 and grew up in eastern Massachusetts. His academic training was in philosophy at Yale (bachelor's degree) and Harvard (master's and doctorate). At Yale, he also immersed himself in analyzing theatre plays. Around the same time, he studied advanced music (piano and clarinet) at the Sorbonne in Paris. He was also a product of this time, with a passion for social change.

Throughout his career, Schön drew on the interaction between (a) his training in philosophy, in particular epistemology and Dewey's theory of inquiry for transforming indeterminate situations into more manageable situations; (b) his appreciation of music, in particular the practice of improvisation in jazz ensembles; (c) his passion for social change, in particular the issue of how its messiness defies the canons of instrumental rationality, and (d) his appreciation of organizations as theatre plays, in particular how the exercise of power can be understood as being informed by scripts. Early on in his career, he was also deeply exposed to work at the Tavistock Institute in London on organizational research and intervention.

After his studies, Schön started working as a management consultant at ADL (Arthur D. Little) in Boston, at the time one of the pre-eminent consulting firms focused on technological innovation. His collaboration with Raymond M. Hainer, a scientist at ADL, profoundly influenced him, and he pointed to his intellectual indebtedness to him throughout the rest of his career. In 1963, he published *The Displacement of Concepts*, later published under other names, exploring how people get to new ideas and pointing to the role of the generative metaphor in framing and inquiry during the process of invention. He was recruited to work for the Commerce Department in the Kennedy administration,

in particular in the National Bureau of Standards, with its Experimental Technology Invention Program. In 1967, he published *Technology and Change: The New Heraclitus*, reviewing models of innovation, observing the propensity of organizations and bureaucracies for 'dynamic conservatism' and viewing them as limited 'learning systems'. Next, he founded OSTI (Organization for Social and Technological Innovation), a consulting firm, where he explored, among others, the organizational difficulties in translating invention into innovation and organizational change. In 1970, he was invited to give the Reith Lectures for the BBC. This led to *Beyond the Stable State* in 1971. He combined the observation of a permanent change in the external environment at increasing speed with the need to radically transform individual and organizational learning. Rather than seeing organizations in a merely instrumental way, he also saw them as learning systems and political entities.

In 1968, Schön became a lecturer at MIT's Department for Urban Studies and Planning, and in 1972, he became the Ford Professor of Urban Studies and Education. In this period, he began a close collaboration with Argyris from Harvard's School of Education (later Harvard Business School), culminating in two books: (1) *Theory in Practice: Increasing Professional Effectiveness* (1974), on the interpersonal skills needed for inquiry into professional practices, and (2) *Organizational Learning: A Theory of Action Perspective* (1978), on the interpersonal skills needed to overcome organizational practices that inhibit organizational learning. Both books provided a perspective on organizational intervention learning in which the concept of the 'behavioural world', both individual and organizational, is the key link between behavioural and professional, managerial and organizational knowledge. A behavioural world can facilitate or inhibit learning (zero-, first- and second order learning). Individual theories of actions patterned on win-lose (which they called Model I) often get in the way of learning, while theories of actions focused on valid information, free and informed choice and learning (which they called Model II) facilitate learning. He emphasized that maps and frames need to be changed for organizational learning to take place at the level of instrumental practice—an aspect often overlooked in the focus on individual behaviour and action. Both Argyris and Schön focused on the quality of individual and organizational inquiry that would lead to what Gregory Bateson called 'deutero learning', or learning to learn. While learning within a constant frame (single-loop learning) was not uncommon and was institutionalized, in business organizations, for example, learning to change the frame (double-loop learning) was exceedingly more difficult and rarer. The task of effective consulting,

they proposed, was to help individuals and organizations develop a capacity for deutero double-loop learning in a world changing at an ever faster pace.

In the 1980s, Schön focused squarely on the nature of professional knowledge and how new knowledge was created. Drawing on a wide variety of cases across professions, including architecture, urban planning, business, psychiatry and economic development, he wrote an in-depth critique on the rational model of knowledge with its separation between theory and use, means and end, research and practice. If professionals were true to this model, they would face a dilemma of rigour versus relevance. In order to get out of this dilemma, he proposed turning the view of knowledge creation on its head—rather than seeing practice as the application of theory, he proposed to see knowledge created as emerging when highly skilled practitioners are in difficult situations that resist their traditional practices and canons. Caught in such situations, they display a kind of artistry—they can do more than they can tell. Through an often tacit process of 'conversation with the situation', which he called 'reflection-in-action', they make an indeterminate situation manageable. It is this process of improvisation and on-the-spot experimentation in the situation that he described in detail, showing how such a process of multiple design moves accompanied by intended and unintended consequences has a rigour in its own right. He proposed reflection-in-action as the core of an epistemology of practice, as opposed to an epistemology based on rigorous research and instrumental thinking. In 1983, he published *The Reflective Practitioner*. In 1987, he published *Educating the Reflective Practitioner*, challenging the traditional relationship between universities and professional schools and showing that practices such as the architectural studio and medical education have strands of learning predating the formation of the current US version of the German research university. He advocated that professional schools should incorporate versions of such practices into their curricula.

In 1990, he edited *The Reflective Turn*, an anthology of case studies by scholarly consultants and researchers grappling with the messiness of organizational and institutional life. In 1994, when he was head of the Urban Studies and Planning Department at MIT, he published with Martin Rein *Frame Reflection: Toward the Resolution of Intractable Policy Controversies*. Based on a review of in-depth case studies ranging from homelessness in Massachusetts and pension systems to introducing computers in the classrooms at MIT (Project Athena), the authors focus on the discourse around intractable policy controversies, the stances proponent take (talking from their frame) and how, in admittedly rarer cases, some policymakers often caught in difficult situations are able to engage in frame-reflective

discourse and in the process reframe the situation. In the mid-1990s, Argyris and Schön issued a paperback edition of *Theory in Practice* and a revised edition of *Organizational Learning II* (1996), drawing on their own insights resulting from research, consulting and teaching as well as on the work of their students.

Through the 1980s and 1990s, Schön continued to teach the core course in the Urban Studies and Planning Department, often with Langley Keyes; to conduct a research course in design with, among others, John Habraken, Larry Bucherelli, Jean Bamberger, John DeMoncheaux and a host of other design faculty and students from across MIT and to teach and develop a hands-on master's course in business leadership at Duxx, in Monterrey, Mexico, informed by design thinking and reflective practice.

Overall, his career of four decades after his education is best conceived as a set of four periods in which various key themes come to the fore through inquiry and publication. During the first period (later 1950s to late 1960s), invention and innovation featured prominently (influenced by Hainer). In the second period (late 1960s to late 1970s), he inquired deeply, with Argyris, into the individual and organizational behavioural worlds in which invention and innovation are played out. In the third period (late 1970s to late 1980s), he focuses on in-depth inquiry into the nature of practical and professional knowledge and how to teach it working with colleagues in the MIT School for Architecture and Planning. Finally, he turned to intractable policy controversies with Rein. In the process, he reached across many institutional, professional and academic boundaries rather than focusing on one specific discipline or field of function. Not surprisingly, a colleague of Schön described him as the 'fox' in Isaac Berlin's 'The hedgehog and the fox', whereby the hedgehog knows one deep truth and the fox knows many.

The early themes of his career—epistemology and inquiry into indeterminate situations, musical improvisation and artistry, social change and messiness, power and conservative mediocrity—were always there. When Schön passed away prematurely in 1997 at the age of 67, he had in mind a publication that could be a career capstone—a contribution to action research and Action Science.

SEARCH CONFERENCE

Search Conferences are a much used action research form that shape arenas for participative planning and development. The theoretical model behind a Search Conference is a participative process aimed at combining a description of a problem area with the development of a vision for a desirable future. In addition, a Search Conference also generates diverse strategies and actions aiming at reaching desired goals, collectively prioritizing the best strategies and forming plans for implementation. In short, Search Conferences help develop understanding of a problem, prioritize what is important and ensure that someone starts working actively to reach the desired solutions. The Search Conference is a method which has its origins in action research, and research groups in Norway and Australia have dominated its development. The first Search Conference in Norway was carried out in a fishing community and was aimed at developing strategies for development of business and social life in this active coastal community. The main actor in the development of Search Conferences on the Australian continent has been Merrelyn Emery, but now Search Conferences have been held on almost every continent.

The Overarching Structure

A Search Conference may ideally last 2 days. Two sets of factors are important in this regard. First, a 2-day

conference allows participants to establish relations, because they will then, among other things, have dinner together and will often be staying in the same place. When a Search Conference is held in a place where participants can stay the night, it has the benefit that participants are removed from their daily tasks. This allows them to focus all their attention on the conference. The evening and night also give participants time to reflect and learn from the challenges and learning that the first day has contributed. A smart routine is to start the next day by asking whether anyone has pondered on anything or has any new ideas since the previous day. This often gives rise to many exciting ideas.

In principle, a Search Conference starts with the identification of a problem area, and it ends with the generation of concrete projects to meet the challenges that the conference has brought to light. Activities in a Search Conference are, as mentioned, divided between presentations and discussions in the plenary session and work in groups, and the group work is usually conveyed to all participants in plenary.

The Search Conference is led by a staff of professionals (at least two people). In addition, it is often natural to involve key local players. The local participants can contribute local knowledge which is necessary to select the right stakeholders, but they can also function as a doorway to the local community.

Selecting Participants

The first challenge for a staff that is organizing a Search Conference is selecting participants. A basic feature of the selection process is to find people who reflect as many aspects or interests of the issue in question as possible. It is important to make every effort to give all relevant stakeholders a voice in the conference. For example, in a conference that relates to a local community, participants should include children, youth, politicians, business managers, active women's groups and representatives of public administration. Thorough work must be done in selecting participants based on an assessment of who is important with respect to the specific issue at stake, and the potential participants must be judged to have the ability to co-operate in learning and planning processes. It is also important that the staff responsible for the conference establish as good an understanding as possible of the organization or community that is the focal point of the conference. One possible way of doing this is to interview all potential participants in advance, who will give the staff an understanding of who they are and an opportunity to convey what the Search Conference involves, and to motivate people to take part.

Staging

In the first phase of the actual Search Conference, the staff introduces the direction or focus of the activity. It is up to the organizers of the conference to decide whether to keep a tight direction of the topic or to have a more open process. For example, in co-operation with the Canadian Aviation Authority in Alberta, a Search Conference was held in which the topic was 'Increased Efficiency and Safety in Regional Aviation'. Such a precise definition of the topic implies tight direction. In a community context, it may be equally appropriate to announce a general theme concerning a desirable future for the inhabitants. The topic of a Search Conference must, of course, be clarified with the initiating groups. A common way of starting the search is to let a local respected authority of the area (e.g. a mayor, an important professional or a local hero) frame the conference. This will be the first introduction, where everyone is together in the plenary setting listening to the presentation.

How Is the Problem Perceived?

At this stage, conference participants are divided into homogeneous groups with an assignment to describe how they understand and experience the issues at stake. Historical development should also be a part of this description, because it helps locate the current situation in a historical perspective. An important perspective in this group work is that no experiences are wrong or right because the aim is to portray the broad understanding that is held by the participants. Therefore, it is important to encourage participants to create an understanding that includes the breadth of the opinions that are conveyed through the group's work. For example, if the conference is run in a manufacturing company, it may be natural to form groups consisting of operators on the floor, mid-level operations management, marketing and sales and top management. These groups should be as homogeneous as possible. The groups' work is presented in a plenary session in such a way that the span of opinions is presented to everyone. It is important in this phase that the staff does not open up for a discussion of what is right and wrong but only gives participants the opportunity to ask clarifying questions. All the groups present their work, for example, by conveying the main points on flip charts. All the flip chart presentations are put up on the wall in the plenary hall and remain there throughout the entire conference. This allows participants to refer back to the broad understanding of how the problem was perceived.

Problem Definition and Desired Future

The next step is an assignment where group members are asked to work on how they see the challenges for

the future. Work is carried out in the same homogeneous groups as in the previous phase. Again, group members should be encouraged to actively support each other in order to provide a basis for broad problem clarification. The objective of this process is to identify what can be seen as the problem situation or definition of the problem. Visions of desirable futures can be woven into this phase, but some process leaders prefer to separate problem definition and visions of desirable future into two different phases in the course of the Search Conference. In both cases, the results of the teamwork are presented in the plenary. Also, at this stage, it is important not to open up for discussions of what is the right or wrong understanding of what characterizes the problem. The first day of the conference ends with reporting out from this problem-defining assignment. In the evening, participants will often have dinner together, and there is opportunity for discussion throughout the evening.

Staff's Organization of the Day's Work

During the evening, the staff prepares the next day's work. The staff's challenge is to organize the input from the first day's work so that consistent categories are developed. Attention is directed at placing the visions of desirable futures in consistent categories that are meaningful to the participants. If it turns out that problem definitions merge into visions of what a desired future is (which may often be the case), it will be natural to integrate them under 'desired futures'.

A significant professional challenge for the staff is to understand what meaning the participants attach to their utterances in order to create categories of the contributions from the groups in a way that makes them recognizable to the participants. An absolute requirement is that one keeps all text (as it is written on the flip charts) in its original form. This organizational process is demanding and challenging work, which often leads to little sleep for the staff. The second day of the conference starts by sharing the staff's organization of the previous day. Special attention is devoted to understanding the different perspectives on what constitutes the problem in focus.

Assigning Priorities for Central Challenges

The second day starts with the staff asking participants whether they have thought about other factors related to the issues at stake, or if they have anything else that they would like to contribute. This could be either new perspectives or a further reflection on earlier presentations. Then, the staff explains its reasons for the organization and tests if the structuring categories are in line with the participants' way of making sense of the situation. It is not necessarily a requirement that

all agree on the way the actual categories structure the problems at hand. Opinions are now sorted by prioritizing what is important. If there are elements that participants do not recognize or that they disagree with, these will simply be issues that none of the participants would vote in favour of. The assigning of priorities can be carried out in different ways. An important challenge for the staff is to understand how disputed some topics can be. If it is likely that a discussion cannot be carried out in a plenary session, it is important to stop the discussion and let it continue in groups. This is an assessment that the staff has to make. If this is the case, it may be relevant to use groups which represent a cross section of participants. Regardless, the result of this process is a list of problems in ordered priority. In this phase of the conference (with a plenary session), visions of desirable futures are presented in different categories of prioritized tasks. This list forms the basis for the next step, which is to develop alternatives for action.

Developing Alternatives for Action

There are several ways to approach this phase. To summarize, the purpose is to bring the visions of desirable futures as a goal for concrete problem-solving activity. At this point, participants are in a plenary setting, where the prioritized visions or problems, which now have become development projects, are conveyed by posters or flip charts which are taped up on the walls of the room. Perhaps the most efficient way of manning the various development projects is to let participants 'vote with their feet'. This means that participants sign in on the poster that presents the topic they are most interested in. Thus, groups are formed which can immediately start working on concrete alternatives for action. Each group will make a plan for implementation. This should include a project plan which identifies who will take part and how the project will develop over time (a milestone plan), and an initial consideration of whether it will be important to recruit members other than those who have accepted the challenge at this point. An absolute requirement is that each group has identified who will participate in the first meeting and who would be responsible for calling and leading each meeting. A plenary session with a joint presentation concludes the Search Conference. At the end, the participants have to decide when the first follow-up meeting will take place.

Follow-Up Meetings

After the Search Conference, there will be several groups working to solve the problems that were identified. This is a situation where there are a number of project groups at work. The follow-up meetings have several purposes. First, it is important to co-ordinate

the activities of the various groups so that people can build on and support each other's activities. Second, different groups will have encountered different obstacles and seen alternative possibilities, and this is, of course, information which might be important and useful for all groups. Third, the follow-up meetings create a structure which commits participants to report and subsequently co-ordinate activity. The number and frequency of follow-up meetings depend entirely on the particular development process.

The staff can conclude its tasks by writing a report of the Search Conference itself. In most cases, it is natural for the staff to continue as long as there are follow-up meetings, but after the conference, it is important to create local leadership for the development activities. An ideal development is that the professionals from the staff gradually withdraw.

SECOND PERSON ACTION RESEARCH

Second person action research or second person inquiry is the name often given to action research approaches that involve two or more people inquiring together about questions of mutual concern. In this form of research, the researchers and the research subjects are one and the same. Co-inquirers work together to identify and formulate inquiry questions, to determine the ways in which information will be gathered, to make sense of it and to act on their conclusions. Groups are small enough to have some significant relationship with each other, traditionally meeting face-to-face, although use is increasingly being made of online and virtual inquiry groups. Second person inquiry is widely used by action

researchers and could be said to typify the underpinning values of action research, since a commitment to create collaboration, incorporate diverse perspectives and build mutual respect is a fundamental characteristic of this way of working.

The term *second person inquiry* was coined by Bill Torbert in 1998 to describe a particular quality of conversation and was subsequently developed by Peter Reason and Hilary Bradbury in their 2001 *Handbook of Action Research* to mean all forms of collaborative, face-to-face inquiry. However, this way of working became established at least two decades earlier as 'new paradigm' researchers sought to find creative and collaborative ways of conducting research with human subjects who acknowledged, and even celebrated, their humanity and capacity for self-determination. Second person inquiry encompasses a wide range of practices from one-to-one conversations to large-group inquiry processes. The thinking behind this approach and significant variations in this range of work are explored below, together with the main skills required for this sort of action research practice.

Second person inquiry holds a particular place in the action research field because it claims that there is a form of knowing that concerns people in relationship with others. The idea of research *with* people rather than *on* them is held as a strong, informing value. John Heron, among others, argues that it is logically absurd to hold researchers as autonomous, meaning-making human agents but to treat the human subjects of research as if they are not equally self-determining. Mainstream research imposes meaning on human behaviour from the outside, as if researchers know what people are doing better than they themselves can. Furthermore, people are more than just thinking agents: They are sentient beings, who draw on experiential, symbolic, expressive and practical ways of knowing their world in addition to propositional sense making. Inquiry into the human experience, therefore, should try not to reduce all knowing to rational thinking. Humans encounter each other in ways that are tacit and cannot fully be described in language: The experience of relationship between persons, the act of encountering each other, is a vital and informing part of human life that is an inextricable part of how the world is understood and how knowledge of it is generated. Although there are certainly aspects of second person inquiry that draw on rationality, conversational approaches to inquiry that draw on a pragmatic tradition stemming from Dewey, at its fullest it is much more than group work or 'putting heads together' to solve problems: It is a way of trying to access and honour the tacit knowing of relationship, where experience is not.

There is also a political dimension; knowledge and power are tightly linked: In so far as the researcher is

claiming knowledge of another, she or he is exercising power over that person, exercising the right to name the other's experience for them. This is seen as one of the ways in which the voice of the elites that dominate academia shape and categorize everyday reality for those without such access. To engage in collaborative inquiry is an act of resistance against such an exercise of power, and a claiming by all those engaged in the inquiry to understand and speak for themselves. In this way, second person inquiry—along with other forms of action research—seeks to include voices of less powerful individuals and groups that traditionally have been excluded from systematic knowledge making. And since the act of recognizing and naming one's own experience in collaboration with others is an affirmation of individuality and autonomy, this in turn can contribute to the political emancipation of those involved. There are echoes here of the process that Paulo Freire called 'conscientization'.

It is not suggested the individual inquirers know their own experience in ways that are free from distortion or self-delusion but that, through interrogating that experience alongside that of others and in good relationship with them, such distortions will be challenged, clarified and shifted. Mutuality and accountability to each other are seen as ways to move beyond habitual forms of relating and conventional assumptions, to surface, acknowledge and learn from an exploration of experience. Validity in this kind of inquiry does not lie in arriving at objective truth. Rather, it is a negotiated validity, tested against its usefulness in helping those involved in the work address the challenges or dilemmas they are facing, together with the quality of the collaborative process involved.

Although groups engaged in second person inquiry may bear some superficial similarities with focus groups, there are important differences of principle and practice. Focus groups are convened by a third party for their own purposes and are given a topic to discuss. The results of that discussion are then used in ways that the discussants have no control over. Second person inquiry groups involve people who share an interest in or investment in the question to be explored: They may, in some circumstances, be convened by and facilitated by a third party, but their purpose is to meet the needs of the group itself. This may range from relatively casual and emergent co-inquiry through conversation to more formal groups, who spend time contracting on their terms of engagement and negotiating their inquiry question with each other.

Types of Second Person Action Research

Bill Torbert and his associates have developed practices on inquiry through conversation as part of the

work they have termed *action inquiry*. They propose the use of four distinct ways of talking, in order to open up possibilities for noticing and questioning the assumptions people hold about each other and increase the amount of overt and shared questioning. These are (1) framing—explicitly stating the purpose and context of the conversation, (2) advocating—setting out an opinion or desired course of action, (3) illustrating—giving a concrete example which supports what is being advocated and (4) inquiring—explicitly asking questions which explore the opinions and responses of others. The intention is to uncover the material which in everyday settings frequently goes unremarked, in a non-judgemental and non-defensive way, with the aim of increasing awareness of self and others and so enhancing mutuality. Such conversations may be planned or may arise spontaneously and are usually combined with other forms of reflective first person inquiry.

A more formal approach is Co-Operative Inquiry, first developed by John Heron and Peter Reason, in which a small group, usually between 5 and 15 people, pursue questions of shared concern through explicit cycles of action and reflection, meeting regularly over a period of months or even years. This is a demanding form of practice, in that all group members are strongly held as both co-researchers and co-participants. Issues of contracting, leadership and authority are part of the inquiry of the group, and use is often made of experiential, intuitive and presentational ways of knowing.

By contrast, Action Learning sets are a more pragmatic and contained form of second person inquiry, in which a small group meet with the support of a facilitator to explore questions relating to their work/practice. Participants are usually invited by virtue of their shared area of work—managers in different parts of a company, for instance, or people who have been on the same training course—and the facilitator helps them move through a process of disciplined questioning and reflection on their work.

Less formalized than either of these are various forms of collaborative inquiry and dialogue groups. Again, these have a strong relational aspect—still small enough for there to be face-to-face connection, so usually less than about 40 members—but membership of the group is somewhat more fluid and negotiated than in either of the previous examples: Not everyone is necessarily present at every meeting. Use is made of dialogic principles in which judgements are suspended and open, non-defensive conversation takes place. The aim is to create an awareness of knowing that arises collaboratively within the group as a result of its conversation and inquiring interaction, so that the whole is greater than the sum of the parts. Such groups may have a convenor and/or facilitator, but the

facilitation is in the service of the inquiry of the group, not vice versa.

On a larger scale, there are a number of well-established facilitated large-group processes that aim to create co-inquiry in gatherings that can be as large as 200 or even 300 people. Such practices explicitly draw on systems thinking, trying to incorporate diverse parts of a human or organizational system to inquire into some shared problem or dilemma—partly by helping parts of ‘the system’ that may not previously have been aware of each other’s perspectives to recognize their interconnection and think together. Examples include Marvyn Weisbord and Sandra Janoff’s *Future Search*, the World Café approach of Juanita Brown, David Isaacs and others and Harrison Owen’s *Open-Space Technology*. These are usually timetabled events lasting 1–3 days, which seek to reach decisions in real time. Participants move between small groups, to explore issues in depth, and the large group, supported by visual or verbal mapping of the different perspectives within the room. As in the smaller groups, the processes involved are designed to encourage the suspension of judgements, draw learning from the experiential encounter of collaboration and prevent the closing down of issues until diverse positions have been heard and understood. Decisions or action points then arise with transparency, if not consensus.

With the advent of user-friendly information technology, increasing use is being made of web-based forms of second person inquiry, with the relational process taking place in virtual space or through ‘blended’ face-to-face and virtual interaction. Action Learning sets linked to formal learning and development programmes are now often conducted by telephone or through web platforms. Accounts are also starting to appear of online co-operative and collaborative inquiry, although there is no strong enough literature base as yet to enable a good assessment of whether the quality of experiential encounter is changed when there is no face-to-face meeting.

Skills

Whilst the concept of inquiring with others is simple enough, significant practical skills are required for collaboration and co-inquiry to take place. Action research journals carry many accounts of the challenges encountered by practitioners in overcoming hierarchical ways of working and the lack of trust amongst members of inquiry groups to achieve a quality of relationship that supersedes everyday assumptions and patterns of behaviour.

Many second person inquiry processes are initiated, led and shaped by an individual or small group, who then have to find ways to balance leadership and

collaboration as they are joined by others. The first steps in making invitations and starting an inquiry can easily establish patterns of ownership and dependency which are unhelpful for co-inquiry. Awareness of group process and basic facilitation skills are needed so that all participants are clear about their contract with each other. Ethical questions will also arise: how to support co-inquirers who feel exposed or vulnerable, how to deal with conflict, where the boundaries of confidentiality lie and who owns the knowledge generated by the inquiry.

Good second person inquiry requires mutuality and trust. All participants, therefore, need self-awareness and openness and the ability to establish empathetic relationships.

SOCIAL ACCOUNTABILITY

Social accountability can be defined as an approach in which citizens or civil society organizations hold public institutions (institutions established by law and statute and funded by public money) accountable. It is an ongoing and collective effort by citizens or civil society organizations which bridges the gap of electoral accountability. Through social accountability, public institutions instead of being indirectly accountable to citizens (via independent government bodies or a special wing of a government department, e.g. Vigilance) become directly accountable to citizens.

Citizens, civil society organizations and sometimes universities collaboratively take up social accountability, which involves data gathering about the performance of the government from the community and government departments. Social accountability can be considered a form of action research as it raises

awareness about poor accountability in a political system amongst the above-mentioned stakeholders and encourages critical reflection that can lead to solutions. The collaborative learning also creates opportunities for further innovations in social accountability and its replication in other regions.

At the outset, it is important to understand the rationale for choosing social accountability as a means to promote accountability in different political contexts. The history of social accountability explains that the shift to social accountability was not sudden; it has taken quite long for social accountability to establish itself as a credible instrument of accountability. Different types of social accountability mechanisms across the world are described in the next section. The section on enablers of social accountability describes the basic factors that make social accountability successful in a particular social context. The expectations from social accountability are then discussed, as well as the constraints of social accountability.

Searching for Citizen-Centred Accountability Mechanisms

Existing accountability mechanisms including electoral accountability do not give space for the participation of citizens in accountability as government-established bodies are the main instruments of ensuring accountability. In such cases, citizens are mute witnesses to a huge web of accountability procedures, and the only means of intervention is to approach elected members of parliament or attend the consultations convened by government bodies. This route to accountability is long and leaves little room for the articulation of citizens' opinions. As a result, basic services to citizens are delayed, and there are opportunities for siphoning off government funds. These constraints to citizen engagement have led to a search for a shorter route for citizens to directly engage with public institutions. Social accountability is one of the shorter routes which allow citizens to engage directly with public institutions to ensure accountability.

Types of Social Accountability

Social accountability can be divided into four stages based on the public finance expenditure cycle. The examples in the four stages have been taken from Brazil, Mexico, South Africa, India and the Philippines.

1. *Planning*: Public policymaking and participatory planning
2. *Budgeting*: Independent budget analysis and advocacy, analysis of budget for local bodies, gender-responsive budget and participatory budget

3. *Expenditure*: Public expenditure tracking and social audit
4. *Performance*: Participatory performance monitoring, community monitoring, Citizen Report Cards on health and water, citizen charter, right to information and public hearing

These social accountability mechanisms have improved the delivery of basic services such as employment, food subsidy and education to children and checked corruption. For example, through Government Watch Social Accountability in the schools of Naga City, Philippines, the quality of school education has improved; participatory budgets in some municipalities in Brazil have resulted in the prioritization of budgets by citizen needs and social audits of the Employment Guarantee Scheme in India have checked corruption and provided employment to the poor. The changing pattern of engagement between citizens and public institutions has gained prominence in recent times, but it has roots going back to the 1980s and 1990s, when tools such as participatory budgets were tried out in Latin America.

Enablers of Social Accountability

Certain conditions or enabling factors are prerequisites for social accountability. These enablers have been identified as supportive laws and institutions, the power of information, local capacity, local ownership, information and communication technology and the development of coalitions.

Supportive laws and institutions imply the availability of legal provisions and institutions for the articulation of citizens' voices. Disclosure of information by public institutions is vital to social accountability as it helps assess the government's performance with indicators such as the budget for government programmes, the number of beneficiaries and the number of items or resources to be distributed among citizens. Citizens who have an especially long history of marginalization lack the competencies and resources to participate in social accountability processes. So local capacity building is an important prerequisite. Sustained and long-term investment is required not only from the government but also from non-governmental organizations and international organizations in building their capacity.

Local ownership of social accountability mechanisms is important for broad-based participation and sustainability. It has often been witnessed that the community is wary of bearing the cost (human as well as financial) of social accountability processes as the members are not convinced about its effectiveness. Information and communication technology, like the Internet, e-mails, text messages and local radio, has

become an important tool for information dissemination and community mobilization. These media can also be important for monitoring and surveying government schemes.

Constraints of Social Accountability

A deficient democratic structure, rules, policies and institutions can be serious hindrances to social accountability. The multiplicity of institutions and the sharing of political authority across a number of levels from the local to the national to the regional to the global create institutional complexities that lead to democratic deficits, thereby posing challenges to ensuring social accountability. In such situations, citizens simply do not know whom to make accountable at what level. The capacity deficit among government and communities, despite the existence of legal mechanisms, can prove to be a hindrance at the outset. Further, ethnicity, illiteracy and caste or class discriminations exclude marginalized sections of society, including women and indigenous communities, from participating in accountability processes. The support for the initiative in terms of human and financial resources can be substantial, which the poor communities and even the government and civil society organizations in several countries of the world may not be able to afford.

Social Accountability and Action Research

The results of social accountability can be manifold. Social accountability improves the accessibility of basic services such as food, education and employment to the poor. It also activates the existing accountability mechanisms by prompting actions by courts and oversight agencies, for example, ombudsmen, public accounting or auditing bodies or legislative oversight agencies. The reports of social accountability are the basis on which complaints and litigation are filed, which creates pressure on courts and oversight agencies to take action. It brings a bad name to public institutions, which are highlighted in the media and on the Internet, harming the reputation and credibility of the public agencies. It forces them to take corrective action to improve their performance. It also leads to punishments and sanctions of public officials for non-performance. In this way, the performance of public institutions is improved, and citizens get access to facilities offered by government schemes. Thus, answerability and enforceability, the key measures of good accountability practice, are present in social accountability. The experiences of social accountability from different parts of the world need to be adapted as per social and political context. Social accountability takes

citizen participation from 'voting to monitoring' in a democracy, thereby deepening democracy.

Beneficiaries and actors such as students or civil society organizations can use these social accountability tools and bring the working of public institutions into the limelight. Use of social accountability tools will involve action research as they collect data using action research methods. In this way, action research will facilitate change in the working of public institutions—in other words, making them transparent and accountable.

SOCIAL AUDIT

A social audit is a tool to evaluate programmes, schemes and activities, often used by government-run service delivery agencies. As a concept, 'social audit' was introduced in 1972 by Charles Medawar to promote corporate, governmental and professional accountability. The underlying principle of the social audit is that a decision-maker, in any democratic system, should be accountable for the use of power and that power should be used in consultation and understanding with the people who are affected by the use of that power. At a later stage, this concept evolved as a tool, especially among corporations, to report their contribution to the overall development of society and to receive feedback from the community on their contribution.

Some organizations use this tool to evaluate their impact on the environment and employment in case of closure and/or relocation of an enterprise. Initially, these evaluations were completed without a shared structure, method or criteria, and the concept was used

more as a social concept than as an economic concept. Further, community-based organizations use this tool in the interest of the community to interrogate physical and social assets, natural resources and other needs. Recently, some non-government organizations, mostly in the developing countries, have started using this tool very frequently and on a large scale.

The social audit is a process in which the details of the financial and non-financial resources used by public agencies for development initiatives are collected, analyzed and then shared with the community. Different stakeholders, like community people, department officials, representatives of implementing agencies and office bearers of the institution or local government, participate in this audit. The sharing takes place on a public platform. Ultimately, the process provides users an opportunity to scrutinize developmental activities, methods of decision-making, the pattern of expenditure, and more, and it allows people to enforce transparency and accountability in those activities. Social audits strengthen downward accountability and help give voice to the poor and marginalized.

Different approaches are popular in different countries to conduct social audits. One very common approach to conduct a social audit is a 'campaign' linked with awareness generation activities within the community at various levels. In this method, community members form groups, collect information from various sources and develop their knowledge related to various aspects of a particular development project. In this process, they also try to develop knowledge of the respondents (and other stakeholders).

Some government agencies conduct social audits using pre-designed formats. These agencies collect data, with limited engagement of the community, and share that with higher authorities, again with limited engagement of the community. Since this method does not promote community engagement, it also does not generate knowledge among the community members.

Another approach to social audits is facilitated mostly by civil society organizations, in which they engage volunteers, mostly from outside the community, and collect data to share in a public hearing attended by government officials. With this process, they try to generate knowledge among community members and local officials, through engaging external expertise and resources.

A nascent approach is where local governments come forward to conduct social audits in collaboration with non-government organizations (as a third party) and share their contributions with the community.

Some key principles have been identified from social auditing practices around the world. These principles are considered as the pillars of social audit, where socio-cultural, administrative, legal and democratic settings

form the foundation for operationalizing the social audit. These principles are as follows:

- *Participatory*: Encourages participation of stakeholders (male/female, literate/illiterate, child/aged, labour/contractor, donor/receiver, etc.) and sharing of their values
- *Multi-perspective*: Reflects the views (voices) of all the people (stakeholders) involved with or affected by the organization, department or programme
- *Multidirectional*: Shares and gives feedback on multiple aspects
- *Comprehensive*: Aims to (eventually) report on all aspects of the organization's work and performance
- *Comparative*: Provides a means whereby the organization can compare its own performance each year against appropriate external norms or benchmarks, and provides for comparisons to be made between organizations doing similar work and reporting in similar fashion
- *Verified*: Ensures that the social accounts are audited by a suitably experienced person or agency with no vested interest in the organization
- *Disclosed*: Ensures that the audited accounts are disclosed to stakeholders and the wider community in the interest of accountability and transparency
- *Regular*: Produces social accounts on a regular basis so that the concept and the practice become embedded in the culture of the organization covering all the activities

Social audits are an important tool to promote accountability. However, they also promote the participation of the people, transparency of the system and responsibility of different stakeholders. In this way, they try to inform various stakeholders about their duties and roles. As a social audit is an ongoing process and can be done at every stage, from the planning of an activity through to the implementation, monitoring and evaluation, any potential beneficiaries or stakeholders related to an activity or project can get involved at any stage of a social audit.

Social audits have the potential to check malpractices and encourage the accountability of the individual(s). Non-compliance with rules and regulations and incidents of corrupt practices, identified through social audit, can be highlighted through the publication of reports.

Where a culture of silence exists, partly out of ignorance and partly out of dependency, strong-arm tactics by government agencies, the conflicting socio-economic

interest of a society and limited availability of data may discourage social audits. Further, social audits can be expensive and may require extensive human and financial resources.

Experiences related to social audit show that extra efforts are required, along with statutory provisions, to promote transparency and accountability in various public institutions. The demand side (community) needs to be strengthened by generating awareness, building capacities, mobilization and facilitation of entitlements. The supply side (service delivery agencies), primarily responsible for follow-up actions, should be supported by creating a non-threatening environment and capacity building in record keeping. It is also important to give actual power to local governments because accountability cannot be fixed without power.

The large-scale involvement of community-based civil society organizations in social audits can have a great impact on the relationship between government and non-government agencies in the future, which currently varies from conflict at one end of the spectrum to collaboration on the other end.

SOCIAL CONSTRUCTIONISM

Over the past 50 years or so, the assumption in social theory and in the social and behavioural sciences that what is ‘out there’ is an already well-made reality simply awaiting our discovery of its basic building blocks, along with the rules, laws or principles of their configuring and reconfiguring, has been challenged by scholars from a number of major disciplines and sub-disciplines, including philosophy, sociology, psychology and anthropology, along with

what is called discourse analysis, deconstructive and Foucauldian analyses, micro-sociological analyses and many others. All, in one way or another, have challenged the positivist assumption that humans live in an established reality of which they are merely ignorant. Social constructionism—which is sometimes called a theory or meta-theory, sometimes a theoretical orientation, approach or movement—constitutes a ‘turn’ in the sense that it is both a turning away from what went before and a turn towards previously unnoticed features of social interaction as being of importance, along with a whole new set of questions and concepts to do with these features. Central to it is a shift of focus, away from thinking that social organizations can be understood by analyzing them into a set of already naturally given basic things and facts, along with their laws of motion, to a focus on the ongoing, active, living interrelationships between people and the others and otherness in their surroundings, and on the creation amongst them all of what we take such things and facts to be. The formative influence of contexts comes to the fore. This entry discusses major contributions to the development of social constructionism and the relevance of this body of work to the way in which action researchers challenge established understandings and innovate new practices.

Social Construction in Its Own Developmental Context

As a ‘turn’, the origins of social constructionism can be traced back to a number of intellectual traditions, most notably in the sociology of knowledge and social philosophy, all of which put into question the nature of what is ‘out there’ in our surroundings existing independently of us, what we take as real.

Berger and Luckman

The first book to have the term *social construction* in the title was Peter Berger and Thomas Luckman’s influential book published in 1966, *The Social Construction of Reality: A Treatise in the Sociology of Knowledge*, and this is often acknowledged as the origin of social constructionism—at least, in its epistemological version. As they see it, things that are ‘real’ for humans, for example, social institutions, are aspects of their experience that are independent of their own volition, or things that are there whether they like it or not—they cannot wish them away. Berger and Luckman defined ‘knowledge’ as the certainty that experienced phenomena are real and possess specific characteristics.

The term *sociology of knowledge*, they pointed out, had already been coined by Max Scheler, but it was

from Karl Marx' earlier work, they say, that the sociology of knowledge derived its root proposition—that man's consciousness is determined by his social being.

It is important to note that Berger and Luckman were careful not to focus their efforts just on the world of theorizers. As they saw it, theoretical formulations of reality, whether they are scientific or philosophical or even mythological, do not exhaust what is 'real' for the members of a society. It is what people treat as real in their everyday, non-theoretical or pre-theoretical lives that must, they said, be the central focus for the sociology of knowledge. For it is precisely this common-sense knowledge that constitutes the fabric of meanings without which no society could exist and function as such. In saying this, they acknowledged that they owed this fundamental insight into the nature of people's everyday, common-sense knowledge of their society's reality to the work of Alfred Schutz.

Alfred Schutz's Critique of Max Weber: From Products to Productive Processes

In Schutz's work *The Phenomenology of the Social World*, originally published in German in 1932 and in English in 1967, he focuses critically on Max Weber's idea that social behaviour can be studied by interpreting the actions of individuals in the social world and the ways in which they give meaning to social phenomena. Schutz is critical of Weber because he fails to distinguish between *actions in progress* and *completed acts*, between the meaning of a situation for an agent in the course of trying to produce a cultural object and the meaning of the object so produced.

Exemplified here is one of the most pervasive, misdirected tendencies in social theorizing: Already accomplished actions are presented retrospectively as a series of well-defined steps towards a foregone conclusion. Prospectively, however, for the actor performing them, they are not like that at all. Nothing is more difficult in everyday life than getting clear—like bringing a severely blurred visual field into focus—the next steps, the ways forward available for one's next move in a still indeterminate situation.

As Schutz saw it, in people's everyday lives, they live immersed in a flow of essentially undifferentiated experiences that melt into one another in a flowing continuum; but this is not how they represent them to others in their theories: Experiences constituted as phases or as noticeable aspects within the flow often become nameable objects of attention for them. These objects are presented to others as such, not by how they have actually lived through the experiences but as a result of their acts of attention. Consequently, people too easily come to treat experiences as separate, nameable, 'objective things' and to ignore the fact that they

are only sustained in existence by being embedded in a larger, unending flow of activity. And this can further, as Schutz pointed out, lead people to ignore the orienting, guiding and motivating influences their experiences can also exert on them, and within them, in relating these experiences to their surroundings.

Dangers of Reification

No wonder that, as Berger and Luckman in fact pointed out, the real relationships between people and their worlds become reversed in our theories. It is only too easy for people in their search for objective knowledge to reify their own nature and, in so doing, to construct a reality which excludes their own agency. Reification, apprehending human phenomena as if they are things, is a very present danger in social theory. Although theorists want to live in a logically ordered world of separate, decontextualized, objective and nameable things, the fact is that in their everyday lives they live within a still developing, undivided flow of activity, amenable to many different orderings. Thus, a social order, both in its development (genesis) and in its existence at any instant of time, is a human product. But this is perhaps to go too far, for to the degree that a social order can be differentiated out of the overall flowing continuum within which it has its existence as such, it is always in *statu nascendi*, always unfinished, continually open to yet further specification and development.

As a consequence, Berger and Luckman conclude that the academic discipline of sociology—as itself an only partly formed social order—is still in formation, and as such, it must be carried on in a continuous conversation with both history and philosophy or lose its proper object of inquiry. This requirement, however, is not always observed.

More Recent Developments in Social Constructionism and Language Use

The same goes for social constructionism as an academic discipline, as a social order still in development. Yet it is often forgotten that our intellectual forms of life grow and develop within an argumentative context, thus we cannot understand the meaning of the claims made within an intellectual tradition or discipline merely by examining the organizing assumptions, ideas, images, or models at work in it only as a structure in itself. As an academic discipline, we must also consider the larger, usually unstated background context within which it 'has its life', so to speak. For the claims being criticized, the alternatives with which it is implicitly comparing its own claims are at work also in shaping it.

Linguistic Social Constructionism

This invisible or implicit background context of everyday activity, within which our more explicit claims are rooted, has not, however, always been emphasized. Indeed, it has been, and still is, more often than not, ignored. Earlier versions of the working assumptions of social constructionism, as set out by Kenneth Gergen, for example, suggested that the terms by which we understand our world and our selves are neither required nor demanded by ‘what there is’, that everything we have learned about our world and ourselves could be otherwise and that how we describe, explain or otherwise represent things in fact contributes to shaping our future.

This led to what might be called a linguistic version of social constructionism, a version with a central focus solely on our ways of talking, aimed at formulating alternative linguistic representations (portrayals, descriptions) of the situations of concern to us. Only now, instead of taking it that our representations are caused in us by the reality around us, the direction of influence is reversed: What we take our reality to be is formed for us by our linguistic representations of it. The idea of a reality existing independently of our volition, as something we cannot wish away, disappears in these assumptions.

This led a number of critics to comment, that although language and discourse are of importance, continuing to ignore or downplay the importance also of our embodied being and of materiality was a mistake. Yet it is still the case that many studies claiming a constructionist provenance merely pay lip service to its philosophical underpinnings and still appear to view social constructionism as being ‘just about language’.

This, however, is to ignore not only the material influences of our use of language on the others in our surroundings but also the fact that we are as materially influenced by our surroundings as we influence them, if not more. And it is this issue that critical realists, as critics of social constructionism, have seen as central. They have suggested that one way of coping with it—while retaining the importance of the linguistic turn—is to put these two disciplinary discourses in debate with each other, in the hope that the best or ‘fittest’ solution to the dilemmas will emerge. But the trouble here is that we still tend to view debate in a Popperian, neo-Darwinian light as not only aiming at a finalized objective knowledge but also being conducted in such finalized forms of talk—Schutz’s difficulty with Weber’s account of action again.

Hacking and the ‘Social Construction of What?’

To put it in more subjective terms, regarding the motivating and guiding influences at work in people

as theorizers or researchers, if the claims being made fail to arouse in them a felt sense of the still invisible ‘yet more’ that they are striving to express (that they need to learn to ‘see’), then they will fail to get their point, in other words, what it is actually that they are trying to draw our attention to in their talk—a difficulty that Ian Hacking outlined in his 1999 book, *The Social Construction of What?*

As Hacking noted, social constructionist talk is now everywhere, and it is easy to get the impression that almost everything people once thought of as solid and well defined is in fact socially constructed. Thus, rather than pre-existing in material structures out in the world, things such as organizations, societies, social groups or families, social realities—along with identities—are all now talked of as being created, as having their being, within language-intertwined interactions with the others and othernesses around people. But what does it actually mean to say that?

Hacking notes that social construction talk is often in reference not only to worldly items, like things and facts, but also to the beliefs and ideas about them. Thus, it is true to say that discussions as to what there is for people in the world depends upon the use of language rather than on the structure of the world, because in discussing language use people are in fact discussing what counts as belonging to the world. Their ideas or concepts of what belongs to the realm of reality are given for us in the language that people use. They see the world around them as much, if not more, through their words as through their eyes. For, if they do live their lives within an essentially undifferentiated flow of experiences, how they pick out and focus on an identifiable aspect of it is crucial to how they can go on to act from within that flow. As Hacking sees it, the world is for people as they present it to themselves through their concepts; thus, if their concepts change, that will mean that their concept of the world has changed too.

But what is crucial here is their use of words, especially nouns, and in particular the word *fact*—for Hacking, it is not so much the tendency to reification that they must avoid but nominalism, a fancy way of saying ‘name-ism’—the tendency to think that when using a noun, it must be the name of some ‘thing’.

Moving Beyond Nominalism and Reification: Staying Within the Flow

More recent ‘turns’ within social constructionism itself have become very wary of this still prevalent tendency to reification and to a forgetting of our ineradicable immersion in the unceasing flow of language-intertwined social activities.

Kenneth Gergen, in his book *Relational Being*, published in 2009, would now like to speak of what

traditionally researchers have seen as an array of independent elements as now having their existence within a confluence, an intermingling flow constituted by an array of mutually defining entities. Others also want to make a similar claim: that social objects and phenomena such as the organization, the economy, the market or even stakeholders or climate change do not have a straightforward and unproblematic existence independent of their language-shaped understandings. Instead, they have to carve them out of the undifferentiated flux of raw experience and conceptually fix and label them so that they can become the common currency for communicational exchanges. So although people still have a very important use for nouns, they teach themselves their different meaning—as picking out aspects within a flowing continuum, not as the names of separately existing things.

This, as Berger and Luckman have indicated, means that people must try to set the starting point for their inquiries within the non- or pre-theoretical world of everyday life, instead of in the worlds of theorizers. But to do this, they need to move back upstream, so to speak, to those beginning moments in the flow of speech communication, in which events of a quite different kind occur than those which develop from them later. Researchers' aim in focusing on these singular events is to try to outline the concrete and unique details of both the creative origins of and the formative processes productive of their more explicit and stable experiences, especially of the intellectual frameworks they construct. Those upstream events, although already partially specified or articulated, are still open to yet further specification, but not just in an 'anything goes' fashion; the next steps possible can only be of an already specified kind—to reify them, to treat them as finished, nameable entities, as indicated above in the section on Schutz, is to lose the motivating and guiding influences that they can in fact exert in our actions.

Conclusion

These tendencies to reification and nominalism are still pervasive in theoretical talk in the social and behavioural sciences, as well as in organizational and management theorizing, especially in the urge to arrive at 'actionable knowledge' expressed in propositional forms. Their influence is especially pernicious in that they can lead us to forget, as we saw above, that organizing is first and foremost an ontological activity, to forget that although a developmental flow of undivided activity is continually at work in our everyday lives, we nonetheless have a hermeneutical capacity to 'bring to presence' the sense of a dynamic, unitary whole from a sequential sense of its parts over a period of time.

Of need of further study, then, as a major topic of action research is how many social phenomena, such as organizations and many other such named entities—which can become closed to innovative development by the reifying or nominalizing effects of current discursive conventions—may be opened up by different uses of language. The question thus becomes for social constructionism whether it can offer to practitioner-researchers and to researcher-practitioners alike concepts and methods of use to them in refining, correcting and elaborating their practices or in innovating uniquely new practices altogether. Or to put the question in a more practice-based, action research context, can action researchers catch the process of social construction 'in the act', so to speak? The study is of importance as researchers need to understand why so many of their academic disciplines and discourses—along with their forms of talk within their everyday social institutions—seem so prone to the tendency of reifying their subjects of discourse and, as a result, close themselves off from further development and become doctrinaire.

SOCIAL JUSTICE

Social justice encompasses an ideal condition in which all members of a society have equal economic, political and social rights and opportunities. David Miller in his book *Principles of Social Justice* contends that in order to become an operable concept, social justice presupposes the existence of a relatively bounded political community with a determinate membership, shared definitions of needs and resources and

some agency such as the state having the capacity to change its major social institutions and thus influence the equal distribution of social resources among the citizens according to the principles enunciated under the concept. Liberal democracies have given birth to the concept of social justice, though its ideas were initially shaped by religious traditions such as Judaism and Christianity. It is mainly in the late twentieth century that it has emerged as a secular concept with the influence of the philosopher John Rawls. A socially just society is based on principles of equality, values human rights and uses democratic processes to achieve these ideals. Action research supports processes to promote democratic social change through participation of the involved community or group. Action research through the co-occurrence of its three elements—action, research and participation—increases the abilities of communities or groups to be in control of their own resources and destinies by overcoming the barriers of class, gender or race and thus function better in a more equal and just environment. By removing the divide between social action and social research, action research is more suitable to nurture processes which are conducive to promoting social justice in the society. This entry discusses the history and development of the concept of social justice, its interrelationship with domains such as rights, gender, polity and the challenges posed by forces of globalization and, finally, the relevance of action research to social justice.

History and Development of the Idea of Social Justice

The term *social justice* was first coined by the Jesuit Luigi Taparelli in 1840 based on the religious teachings of St. Thomas Aquinas. The concept was further elaborated by J. A. Ryan, who was also responsible for advocating the concept of a living wage. John gave a secular dimension to the concept of social justice, and political theorists such as John Stuart Mill, John Locke, David Hume, Kropotkin, Friedrich Hayek, Herbert Spencer and others brought the term into the mainstream discourse.

Two theories explain social justice from two different views: (1) utilitarianism and (2) the contractual theory proposed by Rawls. In its essential form, utilitarianism tells us ‘to perform whichever action among the options available will produce the greatest sum of happiness for all’. Thus, from the utilitarian point of view, certain sets of actions are considered socially just if their application results in greater happiness than any other alternative action. However, utilitarian theory could not account for the distributive character of justice, which emphasizes the fair and equal distribution

of certain rights and opportunities among all members of a society.

Taking on this point, Rawls developed his contractual theory of social justice. To his mind, each member of society has an inviolability founded on justice that even the welfare of society as a whole cannot override. Social justice, according to Rawls, is concerned with the fair or equal distribution of social primary goods—rights, liberty and opportunity, income and wealth—among the members ‘unless an *unequal* distribution of any or all of these goods is to the advantage of the least favored’. He suggested that social justice should be based on two rationales: (1) each person in society should have an equal right to basic liberty and opportunities and (2) social and economic inequalities are not acceptable or justified unless they result in the greatest benefits to the least advantaged. According to Rawls, these rationales are legitimized by following a particular system of collectively enforced social arrangements. In order to ascertain the agreement of the people about an arrangement or a general principle, he advocated a two-step contractual process. According to this process, (1) a majority of the members of a society agree to be represented by a representative for certain actions, and to that extent the representative holds these powers as a trustee of the members’ interests, and (2) the members are bound by the decision of the representative as long as the trust is not violated by either of the parties.

Thus, the same contractual arrangement also extends by the same logic to other territorial bodies, including the nation state, which is the ultimate trustee in this sense. Rawls asserted, however, that the general principles of social justice should arise from the people and not from the lawmaking powers of the nation states.

Taking further the principle of distributive justice, Miller in his influential work *Social Justice* pointed out that social justice was primarily concerned with the distribution of the benefits and burdens of social cooperation within one society. The values of the benefits are to be established by their worth based on a broad consensus among the relevant population. The benefits could be a range of goods, services and opportunities, such as money, commodities, property, jobs, medical care, honours, prizes, housing and so on. Burdens include, for example, military service, hard, dangerous or degrading work and care for the sick or elderly. Therefore, social justice, as Miller argued, was about how these benefits and burdens are assigned to individuals in a society. He advocated three circumstances which should be present for social justice to function as a policy-guiding ideal with political relevance: (1) a self-contained politically organized community with a bounded membership, (2) an identifiable set of institutions whose impact on the life situations of individuals

of the society can be traced and (3) an identifiable agency, such as the state, which can change the institutional structures in approximate ways according to the guidance of the theory of social justice.

Within these circumstances what principles need to be kept in mind for the society to be a just one? In the *Principles of Social Justice*, Miller has put forward three principles that the society must comply with while assigning benefits and burdens to individuals to make it a just society. They are *need*, *desert* and *equality*.

Needs are met by social resources which are set aside for distribution to individuals on the basis of need. Services are provided fully or partially according to a shared understanding among the members of what one must have in order to ensure a minimum decent life in the society. The needs will be fulfilled by a range of institutions such as families, public institutions such as schools, health-care agencies, social security institutions and so on. If resources are scarce to meet a particular need (e.g. food), in order to ensure justice, specific allocating systems will be put in place, and the need will be taken as an important criterion and applied across the whole society for distributing the resources pertaining to the need. For example, measures such as unemployment allowance, minimum-wage legislation or cash transfers can be used to provide adequate security to meet the need of food among the disadvantaged. This is what is called distribution of needed goods on a non-market basis. When social resources such as prizes, honours or positions are allocated on the basis of display of merit or a special talent by the member of the society, it is called desert. Miller suggested that deserts are different from needs in the sense that certain activities will be valued differently because of their qualitative attributes, such as performing well in the arts or contributing to the production of goods and services, based on which individuals come to deserve these benefits. Not recognizing these differences will amount to injustice to such members. The third principle of equality flows from these two in the sense that for social justice to become an operative ideal in a political community or society, the members should be treated as equals in such a way that the income and other benefits people receive correspond to their respective needs and merits. Here, it may be noted that equal treatment need not be identical treatment. Sometimes, failure to provide different treatment because of pre-existing unequal social and economic positions of different groups in itself will evoke instances of injustice. Thus, treating two strong individuals or two weak individuals as equals is social justice. But treating a weak individual and a strong individual as equals is identical treatment, which is not social justice. Miller's argument of different treatment because of pre-existing

unequal social and economic histories of groups is reflected, for example, in the affirmative or positive discrimination policies for certain caste groups in India or for African Americans.

Interrelationships With Other Domains and Implications to Social Justice

What kind of institutional structures, contexts and relationships are necessary to realize the goal of a socially just society? What type of knowledge needs to be generated to understand and make these systems work? How can this knowledge be generated? In a majority of nation states, a formal constitution is the institutional structure that specifies the set of rights that each citizen must enjoy and the rules and procedures for realizing the same. In this context, law becomes one of the instruments to achieve social justice if it is interpreted to keep the justice ideals enshrined in the respective constitution. Miller identified three institutional contexts in liberal democratic societies—(1) the family, (2) the workplace and (3) citizenship associations—where the three principles of social justice—(1) need-based distribution of resources, (2) merit-based distribution of rewards and (3) equality-based access to resources in associations—are realized, respectively. While Rawls and Miller focused on the distribution issue of social justice, some scholars argued that the dimensions of social relationships do matter. Thus, social justice needs to be understood by examining the ways in which the existing social structures and social institutions promote some people and oppress others. Therefore, different forms of social oppression should be understood in the analysis of social justice. Amartya Sen opposed the distribution view by claiming that what matters in social justice is not what resources we manage to distribute fairly to people but to what extent we are able to help people develop their 'capabilities'. Thus, the capability approach directs our attention away from the procedures of distribution of resources to 'what people are actually able to do and to be' to achieve effective social functioning.

While it is important to understand the different dimensions of social justice, its practical implications can be understood only when we examine its manifestation in a range of sociopolitical contexts. Thus, action research as a strategy leads to a critical analysis of the institutional structures, contexts and oppressive relationships with the engagement of the people in action. It would lead to the development of evidence-based action through a democratic process which can make people, communities or organizations realize and put in place social arrangements which are informed by the principles of social justice. Such co-generated knowledge would enable groups,

communities and organizations to challenge the existing hegemonies based on capital, gender, race or caste and change them into more sustainable and just environments. The concept of justice unfolds as practitioners encounter various forms of oppression through research, understanding and action.

For example, during the 1960s, when women contested sexual and gender discrimination; African Americans contested racial segregation, inequality and racialized distribution of resources and Dalits (communities historically marginalized on the basis of *caste*, an ascribed status by birth) in India contested physical and psychological segregation in the form of untouchability, practised in residential, social and cultural spaces, they based their claims for justice on the a priori assumptions associated with social justice. There are other examples of such contexts, for example, gender, human rights and law, health care, bioethics, environment and climate change and the identity issues of the lesbian, gay, bisexual, transgender and queer (LGBTQ) people. In societies which have progressed from feudal to egalitarian societies, the movement has always been interspersed with protests and debates regarding innumerable violations of the right to liberty, expression, association and equality. Exploring these contexts and situations through action research will help us understand how the practical implications of social justice are played out in these contexts.

Social Justice and Action Research

Thus, action research aims at co-generating knowledge with the express purpose of taking action to promote democratic social change. The abilities of involved communities or organizations are increased to control their own destinies more effectively and continue to do so in a more sustainable and just environment. To make the social justice concept socially relevant and applicable to different social contexts, there is a need to build empirical evidence about how the various dimensions of justice are framed and understood by the public at large. Theories of political philosophers about social justice need to be tested against the beliefs of ordinary people so that there is better convergence between what people hold and what philosophers debate about justice. If the aim is to arrive at publicly justifiable principles, then one should look at the principles that people accept about justice and its various manifestations. Action research by its very nature is grounded in evolving theory and action through people's participation. The steps of action research are interwoven with the social justice principles, such as equality, fairness and rights. Therefore, it can play an important role in examining the different dimensions of social justice in its practical contexts and in developing a normative

theory of social justice. Action research can be an important strategy to understand the changing boundary of the concept of social justice and its implications for peoples, contexts and nation states as a philosophical precept.

Prospects of Social Justice in the Context of Globalization

The scope and meaning of social justice underwent a dramatic change in the context of globalization. Globalization is a process where national boundaries have become permeable in such a way that people's lives are affected increasingly by the working of global market changes, on which nation states have little control. Therefore, contemporary theorists of social justice argue that in the context of globalization, the scope of social justice can no longer be limited to the state as a politically bounded community but needs to be extended beyond to the level of global justice across humanity. From this perspective, Miller suggested that nation states need to abide by certain obligations to promote global justice, such as the obligations to respect human rights and to refrain from exploiting vulnerable communities and individuals, and to provide countries with the opportunity to achieve self-determination and social justice.

He further argued that the effects of globalization and multiculturalism on contemporary societies across national boundaries have in fact changed the relevance of social justice in the global context. In the era of globalization, questions about the interrelationship between growth, poverty and inequality will get addressed in a different manner if we ask how the fruits of growth have been shared and whether the processes and arrangements underlying the current phase of globalization are just. First, though globalization is often equated with international equity, Amartya Sen pointed out that there was inter-country equity and interpersonal equity and that they were not the same. The impact of interpersonal equity on people and communities may differ depending on their plural identities, such as race, caste, religion, ideological or sexual orientation and location within nations. Therefore, the notion of global justice may not only be able to capture these impacts under the category of global justice, but also these differences cannot be used to understand the equality or inequality issues between states. Second, if we consider the rules governing the present economic arrangements in respect of the relationship between capital and labour, they are far from just. For example, China received 150 times more foreign direct investment to its economy than any other country, even the USA if we take into account the recent past. Similarly, a small increase in the US wage rates can lead to

changes in the direction of US-based capital in terms of its outsourcing of labour from another country, thus leaving the labour and capital vulnerable and insecure. With the impact of these global forces, the assumption of the nation states as self-contained political entities is increasingly challenged.

Multiculturalism is another manifestation of globalization, where a variety of groups within nation states—religious, ethnic, caste, cultural—assert that their voices and separate identities be given political recognition. When societies are divided along ethnic, religious and ideological lines, they tend to articulate their perceptions about the concept and principles of social justice more sharply. Therefore, it will be increasingly difficult to arrive at shared agreements about social justice. At the same time, globalization makes states' policy options more constrained and difficult to pursue in the direction of social justice. When political communities within the state are sharply divided along diverse identities, it erodes the state's capacity to direct the major institutions and resources due to the perceived differences in the definition of social justice. Action research is well positioned to understand these challenges. Finally, Hayek argued that the more powerless the state is to intervene in the distribution of the resources that the global market creates, the more impossible it becomes to pursue social justice in practice. Many scholars contend that social justice is a lost cause in the context of global economy, and as Miller pointed out, that one might well drop the idea of social justice from the political vocabulary and stop constructing elaborate theories on the basis of it. Though he used strong words, it cannot be denied that his observation reflects the current debates about the prospects of social justice at the global level.

SOCIAL LEARNING

The meaning of social learning is dependent of the field within which it is talked about. Social learning as a concept, theory and approach has come to be an important dimension of action research and even more so of Participatory Action Research.

The Diverse Theoretical Sources of Social Learning

The roots of social learning as it is now understood in the context of action research can be found in different but related bodies of literature. Social learning does not as such have a linear historical trajectory, but as a concept it takes its sources from a number of academic fields of expertise, such as education, developmental psychology, organizational development, international development and sustainability. Social learning was first articulated in the 1970s as a theory by Alfred Bandura, a development psychologist who focused on how children learn from observing and engaging with their environment, underlying the importance of social interactions in the learning process. During the same period, Chris Argyris and Donald Schön, who worked on organizational development, highlighted the role of organizational learning for organizational change to happen, implying that there is a systemic dimension to learning. The links between learning and change are also central to Paulo Freire's pedagogy and to Jack Mezirow's transformative learning theory. But much earlier, in 1946, it was Kurt Lewin's seminal paper on action research which introduced the idea of the dynamics between actions, research and how social interactions or field forces can stop or foster learning. Nowadays, in the context of international development, and more specifically in natural resource management, social learning is conceptualized as a process of learning collectively to foster systemic changes. Jim Woodhill and Niels Røling consider social learning as a framework to foster reflective critical learning between stakeholders in the context of adaptation and innovation. Meg Keen, who worked with Val Brown and Robert Dyball in Australia, see social learning as an interactive process between, what they call, five braided strands of social learning. (1) Reflection and reflexivity, (2) system orientation, (3) integration, (4) negotiation and (5) participation are five ongoing processes, and the weaving of these strands help generate ideas and solutions to promote more sustainable futures.

The Process of Social Learning

Independently of the strengths and limitations of these contributions to the field of social learning,

what transpires strongly is that social learning encompasses a dynamic process of interactions between people which stimulates learning and should generate some form of transformative change, based on critical reflection and analysis, where power and power relations play a major stimulus. For Freire, change is about creating new and different types of power relationships rather than having a reversal, with the oppressed becoming the oppressors. This is an important aspect of action research and more so Participatory Action Research, where the role of the researcher is to step down from the authoritative position of the expert to become a facilitator of the collective critical learning process. There are a number of different dimensions in the learning process that are emphasized by different social learning theorists. For Mezirow, transformation is key, and learners become able to look critically at their own mind frames and world views to consider others and create new world views which help them to be more innovative and adaptive. The learner should also retain this capacity to keep transforming as new information is acquired which challenges the old worldview. For Ira Shor, knowledge has to be reinforced by a critical dimension where learners become aware of what holds them back and what prevents them from achieving transformation. Chris Argyris and Donald Schön conceptualize learning as a process of moving through a succession of learning loops where the learner moves from following the rules (single loop) to changing the rules (double loop) to eventually learning about learning (triple-loop learning). Critical analysis is essential to move between the loops. Meg Keen and her colleagues have adapted this model, whereby the single-loop learning from an event leads to action, the double loop leads to questioning or changing the governing assumptions and the triple loop leads to reconsidering the governing values. This step is akin to Mezirow's level of transformation. Finally, the other dimension of social learning, which runs through most of the work on adaptive management, is the acknowledgment of *interconnectedness*: People are connected to each other through very complex and dynamic relationships, but people are also a part of systems, such as the social, environmental or economic systems. And, thus, while poverty or environmental degradation, for example, have multiple roots, they cannot be solved through unilateral actions. Rather, they need to be understood through different disciplines as well as through the lenses of multiple social actors.

From a social learning point of view, action research mostly makes sense if it leads to social change and transformation. Rölting has written about the need to develop a collective distributive cognition. Unlike shared cognition, where people share values which lead

to collective action, collective distributive cognition draws on different viewpoints from a diversity of value systems and builds on this diversity new understandings of the context in crisis and new creative ways to resolve the crisis.

Social learning is therefore more than just the result of social interaction. It also involves profound intrapersonal analysis and the decision to act for change. Social learning needs to be facilitated in order to stimulate not only exchange, sharing of knowledge and creation of new knowledge but also critical analysis to develop what Rölting calls concerted action. To a large extent, there is a capacity-building dimension in social learning as people should learn the skills to keep on being able to learn and adapt. Participation is also an important concept or set of values underpinning social learning, with citizen participation and empowerment very much on the social learning agenda. Participation has been widely and at times rightly criticized for its mechanical implementation in a depoliticized way. In the context of social learning, however, it is considered as transformative participation, where politics, social justice and power are constantly being scrutinized; it is understood as praxis in the Freirian sense.

Promotion of Social Learning

Whilst at some level, learning from one another through social interactions is what humans do, it does not just happen. For learning to gain a richer texture and to be transformative, it needs to be fostered and facilitated. Careful facilitation of the weaving of the five strands is needed, and facilitation is a complex skill which is learnt through praxis, meaning that the act of facilitating is underlined by a commitment to change power relations and foster critical transformation during the research process. In the context of Participatory Action Research, the researcher is the facilitator and needs to transform her or his role. The aim of the action research process is to create a space for people to do their own research, data collection and analysis in order to address their own collective problem and dilemma. In the social learning process, the focus is all of the above in addition to facilitating learning on and from the process itself. The aim is not only to facilitate groups to generate subjective knowledge of their own context but also to help them learn how to learn, so that these groups integrate into their own awareness the value of learning and the need to continue learning when new challenges emerge. Typically, participants (be they illiterate farmers or highly educated policymakers) usually reflect that the most powerful dimension of participatory processes is the learning that occurs simply by taking part (when the process is genuinely participatory). The social learning

process focuses on making this learning explicit, which is also a central tenet of liberation pedagogy. As Gillie Bolton has demonstrated in her work on reflective practice, transformation and critical knowing happen through reflexivity, which is a deeper process of reflection where one looks at one's own process of thought and analysis and assesses its limitations in a self-critical way. Reflexivity is also a central tenet in qualitative research when researchers need to assess and challenge how their own ontology and subjectivity affect their research process. But here, in social learning, reflecting needs to lead to action in order to foster transformative change.

At a more practical level, facilitation relies on the creative combination of participatory research tools in order to stimulate reflection, discussion, exploration (collective and self) and analysis in a people-friendly, inclusive way, adapting the choice of tools and techniques to the context and the people. Diagrams, maps, calendars, transects, lifelines, drawings, matrixes, and role play can all be used in different ways. At a more strategic level, social learning processes revolve around the formation of multi-stakeholder processes, also often called multi-stakeholder groups or platforms. Stakeholders are individuals or groups of individuals directly concerned by the issue at stake. Stakeholder analysis, a prerequisite to any social learning process, consists of two steps: (1) the facilitator with an initial group of individuals start listing groups/individuals who should be involved and (2) then all the groups together proceed to an analysis of the relationships between all these different groups. It is important to understand not only the power and hierarchies between groups but also the history of conflict or co-operation and alliances. This approach is used in any participatory process or a conflict analysis/resolution process. Then, the groups engage in a social learning cycle such as the one Keen and her colleagues have articulated, whereby individuals and groups (a) diagnose where they are at, (b) create the design by adding new ideas and identifying the skills and resources in hand and those needed, (c) test the design and try out new ideas mixed with old ideas, (d) develop through evaluation and reflection on what was learnt and learn what should or could come next and, then, (e) restart the whole process in an ongoing, continuous way.

Social learning can be facilitated at different levels or scales. Some action research projects funded by the European Commission, for example, have promoted social learning at the European scale, with different European partners working on integrated management and sustainable use of water at the water catchment level. Others apply social learning principles to grass-roots-level community resource management,

for example, work done in Nepal by Hemant Ohja and his colleagues from Forest Action in Kathmandu.

The Challenges for Social Learning

The facilitation of multi-stakeholder platforms has its challenges, since bringing groups of individuals with long histories of conflict or distrust and with apparently conflicting agendas to the same process is not easy. It takes time, resources (financial and human) and a willingness by all parties to address the issue in a collective, inclusive way. As this process also challenges power relations, the most powerful may fear that there is too much to lose. Thus, developing a collective understanding that historical power structures may be a hindrance to moving forward is not a foregone conclusion. Cees Leeuwis and Rhianna Pyburn, from Wageningen University, borrow from Rölting the metaphor of the 'wheelbarrow full of frogs', which the driver has to push skilfully through heavy mud, constantly balancing and rebalancing, possibly changing direction before coming back on the path, in order to keep all the frogs, which are ready to jump off, in the wheelbarrow. In the same way, facilitating the social learning of a multi-stakeholder platform will not be linear and the outcome not predictable. What is predictable is that the group dynamics will be central to the success or failure of the process, and managing these well will be crucial.

Research in education and also experience in the field of social learning and Participatory Action Research demonstrate that people are also resistant to learning beyond the first or the second loop as discussed above, because challenging one's own world views is emotionally destabilizing and can have deeper, ripple effects in one's life. In work conducted in Nepal by the author with women-only user groups on social equity, it became clear that elite women were well aware of how social injustice constrains poorer women from the lower castes. However, they said that implementing a different, more equitable redistribution of resources (rather than giving all an equal share) would create too many conflicts with the upper castes and destabilize the social order. So learning and knowledge do not necessarily lead to action or the 'right' action which will promote social change.

In the daily hustle and bustle of professional life, it is also not always easy for people to make the time and space to engage in lengthy interactive processes which have no clear goal in sight, and so social learning, not unlike conflict resolution, tends to be considered as a last resort when the crisis point has been reached. The Landcare movement in Australia can be considered as the first social learning process on a large scale where landowners started to co-operate

amongst themselves and also with other stakeholders to reconsider land management practices. This was possible only because environmental degradation had become a problematic reality and salinity was destroying their land and livelihoods. This led to tree planting and land management changes, decided and designed by all the stakeholders involved (as opposed to a top-down policy change), on an unprecedented scale in Australia. And it also contributed to building stronger, more resilient communities. It is perhaps also not surprising that social learning has also been more studied, conceptualized and implemented in the Netherlands, mostly around water management, than anywhere else in Europe. Because of their history of community participation, the crucial importance of water as an ally and as a constant threat, the high population density and a deep sense of democracy, the Dutch understand the need to develop a social consensus to work with all stakeholders to develop solutions for more sustainable futures. This is not to say that there need to be social or historical prerequisites for social learning processes to be possible but that understanding the socio-historical, cultural and political contexts is important to setting up strong, inclusive processes.

The Relationship Between Social Learning and Research

So where is the research in social learning? It could be argued that social learning falls more on the action than on the research side and that it is nothing more than a participatory development process with a specific focus on learning. However, it qualifies as a Participatory Action Research process because it generates new knowledge and understanding on the issue(s) under scrutiny as well as on the process itself. As already discussed, researchers become facilitators and step down from their authoritative, expert role, but this does not mean that they forget their knowledge and skills. On the contrary, they will use them to help the process along. Researchers play three complementary roles. First, they are scribes who observe and document the process almost in an ethnographic way, so that we can better understand how these collective learning processes work, in order to inform the next learning cycle and in order to provide evidence to policy and decision-makers of the intrinsic social economic and environmental values of social learning. Second, they are key informants and inform the collective process with general knowledge of the issues at stake or previous collective learning processes (there is no need to let people reinvent the wheel just for the sake of participation). This role provides opportunities to share and disseminate research outputs or to update academic, relevant knowledge amongst end

users, which may otherwise stay locked up in academic journals. Researchers also use their 'expertise' to keep an eye on the process. They make sure the process is inclusive, deal with potential destructive group dynamics, stimulate the critical reflexion and alert the group about structural constraints they may not be aware of. Finally, researchers are advocates who lobby the academic world and contribute to the growing body of evidence which suggests that knowledge that matters is deeply rooted in context and subjectivity and reflects the needs, fears and opportunities of the people themselves. Thus, for these reasons, social learning fits very well as a companion process within action research. And, as with action research, these roles the researcher plays in promoting social learning demand reflexivity, flexibility, respect, openness, creativity, humility, some courage and patience, whilst at the same time maintaining rigour and quality and intellectual honesty.

SOCIAL MOVEMENT LEARNING

Social movement learning refers to both the learning that takes place within social movements and learning about or from social movements. It is a rapidly

growing area of interest, including within action research, and begins with the concept of social movement.

Social Movements

A social movement is a collective of people with a common interest directed towards political and/or social change. Because there must be widespread popular support and active participation, social movements are distinct and different from small, staffed and resourced organizations (like non-governmental organizations) or tiny pressure groups advocating, organizing, publicizing and/or pressurizing for an issue or position (e.g. Trotskyite sects or corporate lobbyists). There has been a growing interest in social movements because they are seen by many as important agents for social change.

For the most part, there is broad understanding of the political nature of social movements and broad agreement that they operate outside of the state. However, there are many areas of considerable disagreement. One such area concerns exactly what it is that social movements are trying to do. Since they usually emerge to deal with some concrete objective(s), social movements are often described as being 'issue' focused. Sometimes, this is accurate and reflects the self-understanding of the members of a movement. However, when a movement is explicitly struggling to overturn the existing order of things, such a description functions to diminish the scope and relevance of the social movement by reducing it to a 'stakeholder' that has a set place in the existing order of things.

Another key area of disagreement is the issue of the politics and democratic practice of social movements. Whilst there is often a widespread assumption that social movements are politically left oriented, many are in fact movements of reaction and intolerance. Even those social movements that are genuinely progressive when they emerge do not necessarily remain that way. Sometimes a social movement is the engineered product/project of a small group of committed activists who need to add social power to their argument or position or theory. Social movements created in this way seldom sustain themselves at the popular grass-roots level. In other instances, a social movement emerges from the experiences, thinking and struggle of ordinary people and is a genuinely grass-roots, popular project. In any case, social movements are invariably dynamic and contested spaces.

Social Movement Learning

As suggested above, for social movements to be social movements at all, the issue or issues they deal with must matter to a lot of people, and these people must

be organized in some way. Further, for social movements to have an impact, the ideas and thinking about the nature of these issues and how to overcome them must also be well-organized, coherent and convincing. Not surprisingly then, there is growing interest in the processes and content of the learning and knowledge connected with social movements.

The relationship between social movements and knowledge and learning emerged as an important theme within social movement theory in the early 1990s. It was argued that social movements define themselves within society precisely in the creation of new knowledge and are thus fundamental determinants of human knowledge. Since then, there has been an increasing interest in social movements as sites of learning. Much of this work has centred on knowledge and knowledge production and has been undertaken by academics or intellectuals outside of the movements themselves. There is thus a growing body of work considering the differences between 'academic' and 'movement' intellectuals.

Academic Versus Movement Theory and Knowledge

It is currently frequently argued that our understanding of the politics and processes of knowledge and theory production within and by social movements is still limited and that movement knowledge and theory tends to be undervalued, whilst 'academic' theory is privileged.

Thus, an increasing emphasis, as with some streams of action research itself, is on work emerging from *within* social movements, and in particular what they have to say about learning and knowledge production. The key difference, it is claimed, is that intellectuals outside of movements produce knowledge about movements, whilst movement intellectuals produce knowledge for and within movements. Some writers have reminded us that much of the theory now widely drawn on by academics was originally produced by movement intellectuals—including Marx and Lenin—who ground their theory in concrete situations and struggle; however, such theory has now been divorced from actual struggle on the ground.

Even *within* movements, two different kinds of theorizing and knowledge production have been detected, related to how the movement was formed in the first place and how it is organized.

Vanguardist Versus Grass-Roots Theory and Knowledge

When a social movement is the engineered product/project of a small group, the processes of learning are often determined by the small expert group who created it (the 'vanguard'). Here, learning tends to be

top-down, and the ordinary members are implicitly or explicitly expected to learn from the experts and to fit their experiences into the bigger theory of the vanguard intellectuals.

When a social movement is a genuinely grassroots, popular project, learning is often open, realistic and transformational because it starts from people thinking about the reality of their life and society. It is inherently a bottom-up, and not a top-down, process of intellectual labour. Such movements start from the assertion that they think (they do not need anyone else to do their thinking for them) and that it is in thinking of the struggle that they create something new, a challenge to the existing order of things. Examples of movements making this assertion include the Zapatistas in the Chiapas region of Mexico and the shack-dwellers' movement, Abahlali baseMjondolo, in South Africa (who refer to the 'university of Abahlali', the space in which they think and theorize their struggle). This insistence of the primacy of the thinking and will of the people is sometimes characterized as anti-intellectualism. In practice, however, most of these movements access and learn from relevant expertise when they need it.

Other Areas of Focus

An area of particular interest in social movement learning is that of the relationship between individual and collective learning, with some theorists arguing that collective learning is a more appropriate lens through which to look than individualized learning theories. This is still a relatively undeveloped area of study. A number of theorists have also emphasized the importance of the women's movement, because it is based on experience as much as theory; it acknowledges emotions as a source of knowledge, not just reason, and it acknowledges that all knowledge is unavoidably fallible.

SOCIETY FOR PARTICIPATORY RESEARCH IN ASIA

Society for Participatory Research in Asia (PRIA, www.pria.org) is an international centre for learning and promotion of participation and democratic governance.

PRIA began its journey as a development organization committed to social change in 1982 and celebrated 30 years on 6 February 2012. Since its inception, PRIA has embarked on a set of key initiatives focusing on participatory research, citizen-centric development, capacity building, knowledge building and policy advocacy. PRIA works with a diverse range of partners at the local, national and global levels. Its professional expertise and practical insights are utilized by other civil society groups, nongovernmental organizations, governments, donors, trade unions, private business and academic institutions.

Vision

PRIA's vision is of a world where informed, empowered citizens participate in the process of deepening democracy, with tolerance towards its large numbers and diversity. These include the marginalized, especially women. Citizens' rights and responsibilities are nurtured through a balance between authority and accountability. A harmony between economic and social development is sought in an eco-friendly manner, where local priorities are not sacrificed to global demands. Individual freedom and autonomy are sustained with collective solidarity.

PRIA's vision of a desirable world is based on values of equity, justice, freedom, peace and solidarity, with a philosophy (Knowledge Is Power) that takes forward all its actions.

Mission

PRIA's mission is to work towards the promotion of policies, institutions and capacities that strengthen the voices against marginalization of communities and increase the participation of the marginalized in society. The idea is to improve their socio-economic status through democratic governance. PRIA's mission is to reach out, through such governance, to everyone in society and to ease his or her participation in the governance process.

‘Knowledge Is Power’ is PRIA’s operating mantra, and organizationally, this means the following:

1. *Valuing indigenous knowledge*
 - Recognizing local, indigenous, practical knowledge
 - Supporting the articulation of this knowledge vis-à-vis ‘official’, formal knowledge
 - Facilitating the systematization of practice-based and experiential knowledge
 - Documenting local, experiential and practical knowledge
2. *Demystifying scientific or macro knowledge*
 - Bringing new, related frameworks, concepts and tools to local knowledge
 - Sharing relevant knowledge ‘externally’ produced
3. *Building perspectives, awareness and skills*
 - Encouraging critical reflection of one’s own knowledge and that of others
 - Motivating self-reflection in the face of self-doubt and confusion
 - Supporting sharpening of one’s own perspectives
 - Building skills
 - Practicing conscientization
 - Handholding
 - Showing one’s own unlearning (and vulnerabilities) and learning from the relationship
4. *Interfacing knowledge mobilization and sharing*
 - Disseminating local, indigenous knowledge to other practitioners
 - Encountering systematization of local knowledge with policy-related knowledge
 - Facilitating network and coalition building with like-minded others
 - Opening doors with the ‘powerful’ to engage
 - Supporting individual-group-collective mobilization for articulation
 - Institutionalizing such indigenous knowledge and its collective production or reproduction

Approaches

PRIA adopts three main approaches in its work, which is crosscutting (across themes and geographical areas) and across different levels (local, meso and global):

First, PRIA intervenes directly in the field in order to promote citizens’ collective voices to make demands on governance institutions to claim their rights, access services and ensure accountable utilization of public resources in development programmes.

Second, PRIA provides on-demand advisory and consultancy services to a wide array of clients internationally. It utilizes its practical knowledge and professional expertise to offer participatory and sustainable solutions to improve the supply side of development and democracy.

Third, PRIA offers educational programmes in human and social development themes, drawing from its field experiences, advisory services and extensive research projects. These educational courses are offered in face-to-face and distance modes.

Trajectory of PRIA’s Work

In its journey over 30 years, there have been some hallmark phases. The work in each phase is not watertight. Many national and international political, economic and sectoral developments from an earlier phase have influenced and shaped decisions in a subsequent phase.

Phase 1: Systematizing Local Knowledge for Empowerment (1981 to Early 1986)

At the time of PRIA’s conception and birth, the planetary arrangement of national and global forces was very specific. In India, at the national level, the new Congress government (led by Indira Gandhi) had come back to power after a failed experiment of the Janata Party government. The Total Revolution movement led by Jai Prakash Narain in the early 1970s had mobilized students and youth on an unprecedented scale. Many such youth groups of the Chhatra Yuva Sangharsh Vahini (‘Student Youth Struggle Brigade’) became disillusioned with formal party politics and set up voluntary action groups around this period.

At the international level, recognition for people’s participation had just about begun following the Food and Agriculture Organization’s Rome conference, which pronounced the criticality of organizations of the rural poor, and the World Health Organization’s Alma Ata Conference, which defined community participation as a building block of primary health care. Nicaragua’s Literacy Crusade had galvanized adult educators in support of liberation struggles. The International Council of Adult Education anchored the regional networks of participatory research, and the First International Conference on Participatory Research was held in Ljubljana, Yugoslavia, in 1980.

PRIA (and its name) grew out of engagement in the International Participatory Research Network. As the node for the Asian Regional Network of Participatory Research, PRIA was active in building knowledge and capacity for participatory research in a variety of settings. PRIA applied the concepts and practice of the international network to its work in India and also

began to actively influence the network and activities of the International Council of Adult Education in the international arena.

The principal activities in the first phase were promotion of participation, use of participatory research methodology and documenting, and evaluating and disseminating indigenous local knowledge. Participatory research activities by PRIA helped promote the following:

- Indigenous knowledge of forest dwellers and tribals around deforestation
- Local knowledge of families displaced due to land alienation and dams
- Experiential knowledge of workers on issues of occupational health and safety
- Lived-in knowledge of rural poor women on questions of literacy and livelihood

Phase 2: Building Competencies as Change Agents (Early 1986 to Early 1991)

In this period, PRIA articulated capacity as learning, learning for empowerment and learning to value experiences and knowledge. This focus on learning as empowerment emerged in practice as follows:

- Participatory training methodology with grass-roots activists and change agents
- Process documentation and evaluation of the projects and activities of voluntary organizations
- Dialogues and consultations amongst social action groups involved in struggles against dams and displacement
- Learning workshops with informal sector workers and their activists in the struggle for health, livelihood and dignity

The principal activity during this period was to use participatory research and adult education in development practice to promote participation—participatory planning, participatory monitoring and evaluation and participatory training. Training of Trainers programmes became vehicles for self-development of change agents in the sector. This helped facilitate critical self-reflection and build competencies as change agents. PRIA continued to be active internationally as an important actor in adult education and participatory research.

A 'code of conduct' for the voluntary sector had resulted in a major galvanization around the country. Mobilization against externally imposing this code of conduct on voluntary organizations created, for the first time, the identity of a 'sector'. PRIA gained visibility as a spokesperson for the sector, with a focus on the

relations between government and non-governmental organizations (NGOs).

Phase 3: Institutional Strengthening of Civil Society (1991 to Mid-1997)

In this phase, PRIA focused on innovation in the development and application of methods and tools for institutional strengthening and learning of voluntary organizations. Three types of activities were carried out:

- Workshops or training programmes for existing grass-roots-level organizations
- Evolution and strengthening of a network of regional support organizations in India and Asia
- Catalyzing new civil society initiatives in underdeveloped regions of the country

Systematic opportunity for learning skills was provided through the training of fieldworkers of grass-roots organizations to build internal capability. Local groups and activists were helped in developing their plans, reviewing future programmes and strengthening internal capabilities and systems, primarily through participatory evaluations, programme reviews and planning exercises.

Learning in workshops needed handholding support in the field; such support had to be practiced as mutual learning (not teaching). Intensive sharing and learning through new networks and platforms of civil society were facilitated for collective identity and empowerment. Sectoral advocacy on promoting participation and empowerment was enabled through systematization of local experiences by monitoring global institutions.

Phase 4: Accountable Panchayats (Mid-1997 to 2001)

The 73rd and 74th Constitutional Amendment Acts were a turning point in Indian democracy, not only because they introduced institutions of local self-governance in the country but also because they instituted a provision for reservation of seats in local government for traditionally marginalized communities (Scheduled Castes/Scheduled Tribes and women). PRIA's experience reinforced the need for people-centred and people-managed development. Decentralized local self-governance provided a constitutionally mandated context for local control over community resources and its sustainable and equitable use for socio-economic development. It is in this background that PRIA began its work in strengthening local self-governance institutions (*panchayati raj* institutions and urban local bodies).

Activities focused around the following:

- Engagements with newly constituted panchayati raj institutions
- *Gram sabha* mobilization for collective participation at the village level
- Capacity building of newly elected representatives
- Strengthening leadership at the grass roots, particularly of women

The flagship programme designed for promoting citizen engagement with the processes of local self-government was Pre-Election Voters Awareness Campaign (PEVAC). PRIA first undertook PEVAC in a few *gram* panchayats of Mandi and Chamba Districts of Himachal Pradesh in 1995. Since then, PRIA has conducted (along with partners) PEVACs in Andhra Pradesh, Himachal Pradesh, Haryana, Bihar, Uttar Pradesh, Madhya Pradesh, Chhattisgarh, Kerala, Karnataka, Rajasthan and Jharkhand.

Internationally, PRIA facilitated local, national and global civil society coalitions and platforms for knowledge sharing and asserting collective and autonomous identity. PRIA co-ordinated the engagement of the southern grass-roots voice in monitoring World Bank's Participation Policy and enabled and supported a global coalition of multiple stakeholders to articulate capacity building of southern NGOs. As a member of the NGO Working Group, PRIA helped organize and implement the policy to foster participation in World Bank projects and the first outside evaluation of those projects. With colleagues from the Working Group, PRIA helped organize the initial meetings of what became the International Forum on Capacity Building.

In the same period, PRIA continued to be very active in promoting the development of international institutions and policies to support the civil society sector. PRIA helped define the conceptual and institutional base for CIVICUS World Alliance for Citizen Participation, which has become the largest transnational network of civil society organizations.

Systematic efforts to engage with academic institutions, departments of social sciences and social work and catalyzing local partnerships with grass-roots civil society organizations have also been made. Academics and students have been trained in participatory research and participatory development for generating knowledge from the experiences of the marginalized.

Phase 5: Governance From Below (Between 2002 and 2008)

As India was 'shining' a couple of years into the new millennium, the Indian government announced the

policy to stop bilateral aid. Voters brought in the United Progressive Alliance at the centre, and the Ministry of Panchayati Raj was created. A series of progressive legislations were enacted—Right to Information, Right to Education, the employment guarantee programme and forest rights. The National Policy on Voluntary Sector was announced. The Second Administrative Reforms Commission was set up to make recommendations on improving governance and administration in India.

PRIA adopted the approach to reforming governance from below and linking local and global participatory governance initiatives under its programme 'Governance Where People Matter'. Multi-sectoral coalitions and platforms were created for shared learning and building a common agenda. PEVAC, PRJA (Panchayati Raj Jagrukta Abhiyan) and continued *gram sabha* mobilization around the country focused on voters' awareness, capacity building of elected representatives and working with state election commissions, state finance commissions and other provincial actors. By convening engagements between the voices from below and the powerful from above, agencies responsible for delivery of public services were brought in direct dialogue with the citizens who receive them. Going beyond a programmatic focus on women's empowerment, PRIA began to focus its interventions on gender mainstreaming institutionally.

Phase 6: Multi-Sectoral Engagements for Deepening Democracy (Since 2008)

The 'War Against Terror' spread far and wide. Global coalitions of civil society worked together to 'make poverty history'. As fuel, food and financial crises hit the world, European and North American economies faced meltdowns. Citizen protests demanding equality and freedom spread in the Arab region; the 'Occupy' movement occurred everywhere. International development assistance in India has been curtailed, and changes in the tax regime and mode of funding of civil society have posed several challenges for the non-profit sector in India.

PRIA's work on promoting social accountability practices for reforming institutions to make them deliver their mandates has come at a time when the government has been caught in webs of corruption. Civil society movements galvanized youth around the country to demand greater accountability of all public institutions, officials and leaders. With rapid urbanization in India and Asia, mobilizing the voices of the urban poor has also become an urgent agenda for action for PRIA.

As new practical experiences become available and new information technology becomes accessible, PRIA invests in systematizing practice at the grass

roots to enable distance learning for practitioners. It has supported initiatives to establish mutual learning engagements between the grass roots and institutions of post-secondary education through community-university partnerships for knowledge mobilization and sharing.

Pursuing its long held belief that 'knowledge is power', PRIA is using old and new media and communication platforms to continue its journey of systematizing, synthesizing and disseminating local knowledge. The latest example of this is a knowledge portal, Practice in Participation.

SOCIO-TECHNICAL SYSTEMS

The notion of socio-technical systems (STSs) refers to the necessity of taking both social factors and technological factors into consideration in designing and implementing humane work organizations. This approach to systems design grew from European concerns about scientific management after World War II and spread widely around the world in the 1980s with joint management and trade union co-operation under the label of Quality of Working Life. Action research is an essential methodology for redesigning work as different sectors, technologies and employee characteristics require a customized approach. Further, the

amount of time and labour involved in STSs means that the dynamics unique to a particular organization have to be worked through and managed as part of the change process.

By using action research, scholarly practitioners can combine linear planning and problem-solving methodologies with longitudinal observation, analysis and interpretation, made possible by being in the workplace up close and over time. Multiple streams of linear project management for changes coexist with aspects of organization wherein social and technical issues evolve in less linear ways and at less predictable paces. This entry summarizes this type of action research, using six dimensions linked historically to the Tavistock Institute of Human Relations, the research and development organization in London, UK, often given credit for its original formation and early experimentation in workplaces.

Framing the Change Situation

Action research from the perspective of STSs tends to start with plans to introduce a new technology, different work procedures, new products and other aspects of operating a business or providing services. Such strategies require co-operation from employees for alteration in assignments, training, terms and conditions and occupational differentials. Such changes almost always have to do with the organization's regulatory or competitive environment more widely and need to involve bargaining with employee representatives. Industry, commerce, shipping and energy are the sectors in which this framing of change originated.

Role of Consultant and Stakeholder in a Typical Change Approach

Scholarly practitioners involved with an STS analysis use design interventions that help people study their own work processes and identify improvements in how the people and technology relate across and between flows of work. The role of the consultant tends to include expertise in elements of diagnosis, analysis and recommendations for particular work organization redesign. By definition, an STS approach includes those with a stake in the outcome in problem-solving and decision-making groups of various sizes and interconnectedness.

Nature of Intervention and Character of Participation

A central orientation of intervention from an STS perspective can be the work organization design. A few, well-established approaches to intervention tend to be

used, sometimes in co-operation with other change management techniques and goals. A long-term infrastructure tends to use organization-wide steering teams, specific design teams for subunits or a series of temporary project teams to design and deliver elements of the change. Alternately, large-group interventions focus on bringing people together in order to design and deliver work restructuring. Participation is of particular importance for STS action research: People who will be working in the new work system must participate, thus building capability to manage STS change through training of internal people and including their views throughout.

Dynamics of Social Stratification

Management of boundaries and collaboration within and across boundaries are two phenomena of particular concern for STSs. Another way of saying this is that work is understood to take place within and across boundaries—points where two or more things intersect. Managerial roles tend to be redefined in terms of managing outwards towards the environment of the work being redesigned, while managing inwards within the focal work tends to be self-managed by groups or by shallow hierarchies within shared roles and responsibilities. One of the ways in which the latter is achieved is through inter-professional or inter-occupational groups. The assumption is that psychological and political dynamics will be less frequent to the extent that people control their own work together. Also, unnecessary differentials in terms and conditions may be removed in favour of group-based measurements and rewards as a way to decrease conflict and envy.

Intra-Organizational and Inter-Organizational Issues

Action research from an STS perspective typically focuses on intra-organizational change and development. A major purpose of STS action research is creating a humane design of work and enhancing the focus of the workforce on the primary task, while eliminating distracting bureaucracy and hierarchy. Boundaries are drawn at the interface points so that workers have more control over quality. Awareness about strategic concerns in relation to the environment both motivate and maintain STSs: attracting and retaining talented labour, increasing quality and productivity, improving services in terms of better co-operation across roles or other subunits. A shared knowledge about what they are facing in relation to the work outside the organization is seen as essential.

Nature of Work With Feelings and Fantasies as Contribution to Learning for Change

Scholarly practitioners specializing in STSs consider working with feelings and fantasies as they relate to learning for organizational change in two seemingly distinct ways. Emotions about apparently objective elements of the work organization design will be seen as both necessary and relevant. Issues of fairness and equity related to terms and conditions, access to business information and influencing decisions and the necessary resources and education to do a good job all would be acceptable and included in change processes. However, there tends to be little tolerance for emotions that privilege one side having more power over another side.

SOFT SYSTEMS METHODOLOGY

Soft Systems Methodology (SSM) works within an action research paradigm and exhibits capabilities similar to other forms of action research. In fact, SSM itself was developed using an action research approach by Peter Checkland, while addressing complex, messy, ill-structured problems faced by managers, in situations where 'hard systems' approaches such as systems engineering failed to deliver the expected results.

SSM enables understanding of the key stakeholders, and in the seven-stage method that was derived as its earliest version, it analyzes the client, actors and owners involved in a problematical situation and integrates their involvement into the process. Checkland, after extensive work in SSM, also developed a four-stage cycle for simplifying his method, similar to a four-stage approach often used by action researchers: Plan-Act-Observe-Review.

Checkland also proposed a frame and a methodology for research directed to a real-world problem or an area of concern (A), working from a theoretical framework (F), which must be declared by the researcher, and a methodology (M), which is used to formulate and guide the intervention. Action researchers who use a systemic perspective often use the F-M-A model to conceptualize their research.

Judy McKay and Peter Marshall suggest that when adopting the F-M-A model to set up action research, the M in the model should be extended to have a methodology for the research (M_R) as well as a methodology for the problem-solving (M_{PS}) part of the intervention. This helps balance the importance of an action research intervention between conducting research and problem-solving, between theory and practice.

Historical Development: The Three Versions

The first version of SSM is called the seven-step model, developed in the early 1980s. Checkland felt that this model was simple to understand, made it easy to teach the process and helped in its early usage. The seven steps, briefly, are as follows:

1. Experience a situation in everyday life that is considered problematic.
2. Express the problem situation (often using 'rich pictures').
3. Develop a root definition of relevant purposeful activity systems that could help improve the problem situation.
4. Develop conceptual models of the (purposeful activity) systems identified through the root definitions.
5. Compare models developed to the real-world situations expressed earlier.
6. Consider feasible and desirable changes as a result of the comparison.
7. Take action to improve the problem situation.

Activities 3 and 4 were expected to be carried out during systems thinking about the real world, whereas the other activities were expected to be carried out in the real world. This delineation of the 'real' and 'systems-thinking' worlds was not carried forward to the later versions of SSM.

Checkland urges the use of the word *problematical* instead of *problem* when a situation being investigated is messy and needs a systemic inquiry process to learn more about it. The term *purposeful action* or *activity* is used to describe deliberate actions that human beings decide willingly to take in response to their own experience of the world.

As SSM started being used by practitioners, it was felt that reading situations culturally and politically was also important. In the second version of SSM, which has been explained in a book by Checkland and Jim Scholes, two streams of analysis were suggested: (1) a logical stream and (2) a cultural stream. While the logical stream resembled the analysis carried out in the seven-step version, the social and political systems were added to consider the 'roles', 'norms' and 'values' that influence the behaviour of the people involved. The political stream considered the issue of power that affected decision-making. In the second version, Checkland also advised identifying 'clients', who caused the intervention to happen; 'practitioners', who carried out the SSM intervention, and 'issue owners', who took ownership of the issues addressed, as sometimes more than one role could be taken up by the same party.

The third, and more contemporary, version of SSM, which is currently used to address the inadequacy of the seven-step model, to match the more flexible ways in which SSM was being used, uses only four steps. Checkland describes these four steps as follows:

1. Find out about a problem situation (this includes the cultural and political analysis added to the second version of SSM).
2. Formulate some relevant purposeful-activity models.
3. Debate the situation using the models to consider the desirability and cultural feasibility of the changes proposed to improve the situation, and also find accommodation for these changes among the conflicting interests of the people involved in the actions to improve.
4. Take action to bring about improvements.

The latest version of SSM gives the researcher or practitioner the maximum freedom to structure the intervention and is quite close to the Plan-Act-Observe-Review process used in action research.

Key Components of SSM

The key components of an SSM intervention are drawing rich pictures, context analysis using CATWOE (a mnemonic for a checklist for problem or goal definition) and root definition and the development of conceptual models.

Rich Pictures

SSM engages the process of finding out about the problems in the real-world situation and possible resolutions to these using 'rich pictures'. Rich pictures enable the development of the keys to understanding

and resolving the complex problematic human situation in terms of its multiple interacting relationships between a range of factors including criteria, methods and cultural and political risks. Rich pictures enable the depiction of the physical and obvious issues as well as the often ignored, but very important, intangible or more subtle issues.

The rich pictures that evolved from a research project that the author undertook for a post-disaster recovery project in Indonesia are now used as an example to explain an SSM intervention.

The rich pictures developed for the intervention took significant and painstaking work as each one needed to achieve validation from very busy and focused key personnel involved in development projects. In most cases, the rich picture effectively became, in many ways, that person's canvas for his or her life's work, or a recent part of that. The interviews to develop the pictures were mostly carried out on-site at the location chosen by the stakeholders, to best interface with and witness their challenges and problems in situ. This took the author to the outer reaches of Indonesia. In each case, the interviewees were very valuable participants, and they also appreciated the effort and feedback required in each exercise.

The eight rich pictures did evolve a very strong alignment in the processes that emerged from them. The key colour-coded, three-level layering processes that the author introduced to the rich picture process were a valuable improvement on previous traditional use of rich pictures in the SSM process. One of the eight rich pictures is presented in Figure 1 to explain how it was constructed and applied.

Working together with the author, this rich picture was created by the Australian chief operations officer of an NGO involved in the post-disaster programmes being carried out in Indonesia, mostly out of their headquarters in Australia. The key steps or factors drawn out here relate to the importance of the stakeholder engagement, the sharing of objectives within the organization, the programme planning, the importance of the communication process and the need to get an effective process between top-down commitment and bottom-up planning. It also brings out the need for commitment to the project plan and the keys of monitoring and evaluation to achieve sustainable outcomes.

What evolved from these rich pictures was a very clear synergy of steps working through each one to understand the overall situation. These key steps could be reviewed together and consistently through the methodology of the development of the rich pictures. The interviews and extensive notes that were taken were reviewed with each participant separately and confidentially. The key factors, as agreed within those reviews, were then interpreted into three layers on the pictures to provide an overall picture.

What also proved very valuable was the use of the natural precedence of colours, which has been realized in other arts and sciences, in the development of the sequencing and flow through the various timings and precedence guiding project development. So that rather than a flow chart connected by logical, or input to output, systematic positivist-type arrows (which most of these sort of operators just don't work with and may see as too rigid or mechanistic), the same sense of precedence and flow, but with less rigidity, was developed through the intelligent use of colours, much the same way an artist would develop a picture on a canvas.

Colours also have synergies in international use, such as danger, growth, communication, safety and wisdom. That more general understanding and feeling were able to enhance the development of the order of outcomes, or the more human understanding and development of sequences, in both background and key-factor, front-end process and resolution.

This was never seen as an end in itself and crucial to the research, but it certainly did enable the less threatening and more flexible arrival at key process order and communication. In fact, the value of the colour sequence was picked up by all the participants, even in the peer review by Western practitioners in primarily 'hard' project world views. This also enabled development of colour codes for rapid decision location and enactment to sense making in post-disaster response. These colour codes were then used in developing manuals for the project.

As it evolved, this rich-picture approach and outcomes proved as important as, if not more important than, the words and processes that followed. Many of the participants agreed that working through this process actually clarified their own view of their own perspective and experience and gave clearer insight and understanding into their situation.

Once the rich pictures were analyzed in their totality and as some level of saturation appeared, with themes emerging as being commonplace across these projects, more general themes emerged. The key steps for each of the eight pictures were then extracted, and that is when the very strong synergies became clear.

Context

Another of the key benefits of SSM is its engagement of the relevant perspective or context. Context and the world view, or the 'point of view' within which these solutions are to be developed, need to be defined for the solution to be found relevant and realizable. Through the formulation of the mnemonic CATWOE, SSM enables the context of the problem and the proposed solution to be put in a clear and usable context. The value of the solution is then much more

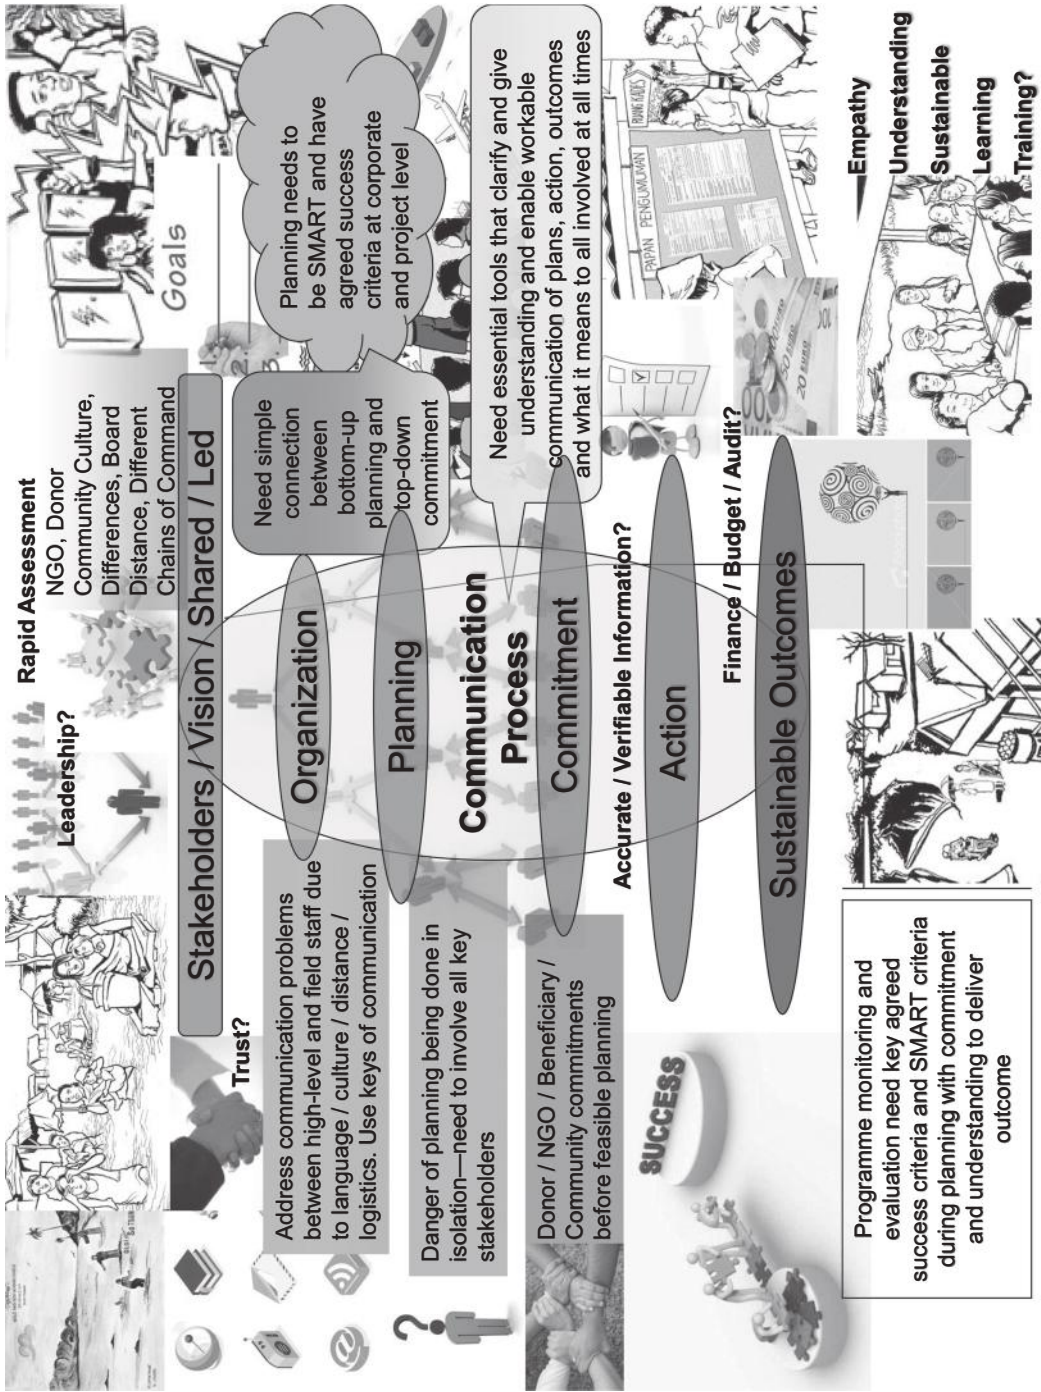

Figure 1 Example of a Rich Picture

NOTE: SMART = specific, measurable, attainable, relevant and time bound.

focused on the situation than if it were simply generic and all-embracing, as usually happens. This context and understanding also bring a much stronger aspect of reality and resolution to the planning of the outcomes.

CATWOE considers the following elements:

- C* Clients, who would be the victims/beneficiaries of the purposeful activity
- A* Actors, who would do the activities
- T* Transformation process—what is the purposeful activity, expressed as an input-T-output
- W* World view or point of view that makes this definition meaningful
- O* Owner or stopper of this purposeful activity
- E* Environment—constraints in its environment that this system takes as given

The CATWOE developed for the post-disaster recovery will help explain its use:

- Client:* Community, donor
- Actors:* Stakeholders, in other words, NGO, donor, community, local government, project manager, aid partners
- Transformation:* Tangible and intangible, in other words, infrastructure, shelter, security, livelihood and knowledge, process, trust, support, empathy, understanding, sustainable and safe future
- Weltanschauung (Why bother?):* Because it is urgently and desperately needed to assess the achievability of planning and implementing an

emergency preparedness/recovery/reconstruction/livelihood project or programme—does it align with the need and group objectives, who are the key and reliable stakeholders, can it be resourced and will it achieve a sustainable outcome?

Owner: Project, programme manager (for) donor, NGO, community (key stakeholders)

Environment: Poor, under-resourced, possibly desperate or endemic context, urgent needs, demanding and possibly hostile environment, need for long- and short-term goals

Root Definition

The root definition helps develop the core purpose of the (purposeful activity) system that helps achieve the transformation to be carried out by applying SSM. The CATWOE mnemonic helps develop a root definition. Later, Checkland also suggested three key context questions related to developing root definitions, often called P, Q and R: (1) What to do (P)? (2) How to do it (Q)? (3) Why do it (R)?

The following root definition was developed for understanding the post-disaster recovery scenario:

A project manager has to rapidly assess the feasibility of competing projects for a community after a disaster or for general aid or relief. This is done for, and in conjunction with, a group of stakeholders to scope, plan and implement (if feasible) a programme or project to enable disaster preparedness or recovery or reconstruction towards a set of sustainable outcomes.

Figure 2 shows how an analysis of the context and the development of a root definition assisted in the

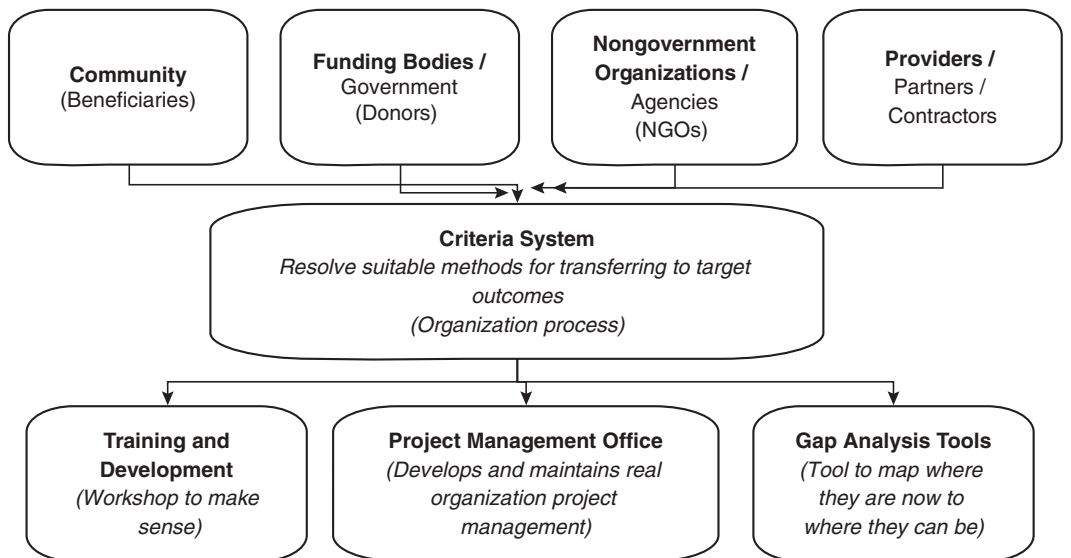

Figure 2 Work Breakdown of the Disaster Recovery Projects

development of a work breakdown for the post-disaster recovery project.

Conceptual Model

In SSM, the conceptual model is a set of purposeful human activities logically put together to carry out the transformation process. In later versions of the SSM, the conceptual model also had to include monitoring and control activities, as well as the transformation

process being subjected to performance checks to ensure that it achieved the intended outcomes (efficacy) with minimum resources (efficiency) that are sustainable over the long term (effective).

For the post-disaster recovery projects, a conceptual model was developed for solution and implementation, as shown in Figure 3.

The final working model that was tested and validated internationally through a number of real-life, in-the-field applications, is illustrated in Figure 4.

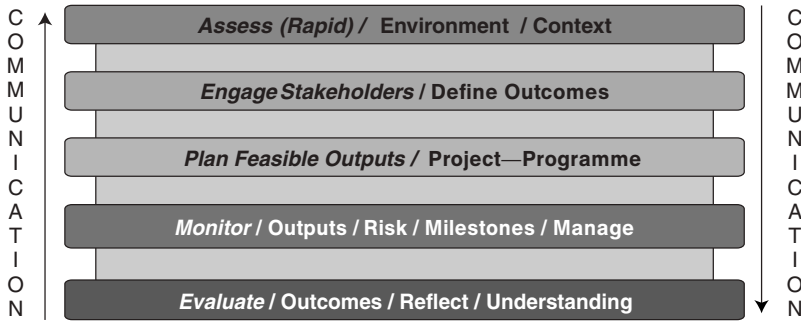

Figure 3 Conceptual Model for Implementation of the Post-Disaster Recovery Project

Figure 4 The Final Working Model That Was Tested and Validated Internationally

Conclusion

The SSM approach is itself a form of Action Learning, and the development of rich pictures is an act of collaborative learning, reflecting and knowledge generation about the studied phenomenon. It is essentially a highly pragmatic research method, with its value and validity based on findings and outcomes that are judged as understandable, workable, useable and acceptable by those who could gain benefit from the research. It has many elements of action research embedded in it. Shankar Sankaran, Martin Orr and Tay Boon Hou have explained how SSM was embedded in action research in two doctoral research projects—explicitly in one and implicitly as a thought process in another.

SSM has been praised for its ability to clarify messy situations using a structured thinking process, but it has been criticized for not providing solutions to problems. Often SSM is combined with a more deterministic back-end process to achieve solutions, and in the example given in this entry, a project management approach was used after analyzing the situation using SSM.

STAKEHOLDER ANALYSIS

Stakeholder analysis is a process or action research methodology used to explore the various opinions that different stakeholders may have on potential outcomes and their relative influence. It is a technique that is widely used for strategic programme planning and policy development. It is particularly popular in the fields of business management, international development and health care.

The term *stakeholder* has a long legal history, denoting a neutral third party that literally holds the ‘stakes’ or assets for interested parties until their rightful owner is determined. However, in the 1960s, the term became popular in the management literature as a deliberate play on words to challenge the notion that corporate decision-makers should take into account only the interests of *stockholders*. The definition was expanded to include those who ought to be considered when management had to make important choices—consumers, suppliers, creditors, competitors and employees. Today, popular usage of the term denotes people, groups or networks that have a vested interest or are affected by or can influence actions.

Depending on the issue under study, stakeholders may include politicians, community groups or organizations, media outlets, corporations, faith-based agencies, funders and donors, academics, resident coalitions, unions, school boards and health-care agencies. They are groups, entities or individuals who are important to hear from when making a decision because they (could) have the power to sway the outcome and may be affected by it. Conducting a stakeholder analysis is a pragmatic approach to understanding who stands to win and who stands to lose from a variety of options.

Stages of a Stakeholder Analysis

Identify Stakeholders

The first step in a stakeholder analysis is to identify the stakeholders. Sometimes, the list is obvious. When the community is small or when you know it well, it can be fairly simple to enumerate the key players. Other times, it may take some legwork. A popular approach may be to start with the most discernible informants and use a snowball approach to grow the list.

Poll Stakeholders

The second step is to ascertain how the stakeholders feel about your issue and their relative power to influence. This can be done through a variety of means. Many stakeholder analysts recommend a qualitative

interview approach. Stakeholders are asked to reflect on their positions (as well as other options), their capacity to make change, the resources they have available and their perceptions of other key actors. Alternatively, a more quantitative process may be used. Stakeholders may be asked to rank several options and/or the relative power of other stakeholders to influence change. Sometimes, a more prescribed approach, such as a Delphi process, is adopted. The Delphi process is one where experts are iteratively polled until consensus emerges. Qualitative methods are often more labour intensive (to both collect and analyze) but are particularly useful for more open-ended brainstorming. Quantitative methods are more expedient but are likely to limit the scope of the conversation. In addition to talking directly to stakeholders, information can be gathered from secondary sources such as websites, blogs, annual reports, newspaper articles and other public documents.

Map Options

Once all the data is collected, the next step is to try to make sense of it. Frequently, stakeholder analysts create diagrams, tables or graphs to map a summary of options. Summary documents often succinctly answer the following questions: Who are your key stakeholders? What is their position on the issue? How influential are they? What resources do they have mobilized? What resources might they be able to mobilize? How impactful are they likely to be? How are they related?

Develop the Strategy

Armed with the knowledge generated from a well-created map, a researcher can then begin to develop an informed strategy. A good strategy will take into account who the ‘allies’ are and find ways to mutually support organizing efforts. It also takes into account who is likely to oppose changes and why. Informed decisions can then be made about whether there are ways to accommodate alternative perspectives in the plan to build consensus or whether to move ahead regardless.

Other Considerations

Stakeholder analyses can be used to retrospectively assess what influences led to a particular outcome. They can also be prospectively applied to assist with future planning and decision-making. They can be done on a macro (e.g. global) scale or micro (e.g. small organizational) scale. Human, financial and time resources will likely set the scope of an analysis. A stakeholder analysis is a way of gathering time-limited information from a range of constituents to help inform decision-making.

How much weight is given to results should be proportional to the efforts inputted. It is always important to recognize that a variety of natural (e.g. an earthquake) and political (e.g. a scandal) factors outside the control of researchers or analysts could radically change the results. Consequently, prospective recommendations are contextually limited. Care should be taken to balance inputs and efforts with the seriousness of outcomes. Furthermore, the reliability of the data is only as good as that of the informants. Stakeholders may purposefully or inadvertently withhold information or mislead researchers for their own political purposes. This will likely result in unreliable predictions.

Unlike other action research methodologies, stakeholder analysis does not have an explicit social justice orientation. In fact, marginalized voices can be easy for analysts to dismiss as they likely have little power to influence change. The concerns of relatively powerless stakeholders may be discounted (even if they are important). Stakeholder analysis has been widely used in business to optimize results for stockholders—often at the expense of other groups. Groups that are likely to be heard are those that have the loudest potential for influence, those that are aligned with the interests of a project sponsor and those that are capable of making change happen.

Nevertheless, the methods can be applied and used by diverse groups to map the landscape for organizational and policy change. It can be an extremely useful strategic planning tool when used appropriately and can be adapted to accommodate more participatory and democratic processes.

STORYTELLING

Stories and storytelling are ubiquitous. There have been human societies and civilizations that have flourished without benefit of the wheel, but none have existed without stories. As recent studies in anthropology,

philosophy, cognitive psychology and neuroscience consistently show, humans are storytelling animals; to be human *is* to tell stories. It follows therefore that the role of the story in action research is critical to understand. This entry introduces the concept of storytelling and asks us to consider these implications for our work as action researchers.

The words *story* and *narrative* are often used interchangeably. However, in this entry (unless otherwise stated) *story* should be taken to mean an ordering of events that infers causal relationships between them, while *narrative* is used to mean the use of words and/or images to convey a story to a listener, reader or viewer. Thus, stories can be narrated (or told) in many different ways and by using many different media, including the graphic arts, song, dance, drama and film. This entry is primarily concerned with the telling of oral and written stories, where the term *storytelling* finds its most direct and literal application, but—broadly speaking—its conclusions can be applied to any form of narrative.

Not all communication is telling a story; humans analyze data, exchange information, proffer opinions, make arguments and plead their case, as well. There seems to be some consensus in the literature that a story is an imagined (or reimagined) experience narrated with enough detail and feeling to cause the listener's imagination to experience it as real.

The Nature of Storytelling

The essence of storytelling is its tangibility: The storyteller seeks to convey an experience (something that actually happened, might have happened or might yet happen) in such a way that it seems real. It might be a story remembered—and perhaps embroidered—from life; it might be a conscious fiction made up about ourselves or others; it might even go beyond what is humanly possible into the realms of folklore, fairytale and fantasy. But in whichever of these spheres a story has its centre of gravity, something has to happen, and it has to happen to somebody (human or otherwise).

Stories necessarily involve particular events happening to particular characters. They sit within a presentational form of knowing that exemplifies experience and offers it to the listener or viewer for exploration. Narratives that veer towards generalities, explanations and abstractions or which insist on conveying their moral or meaning have abandoned storytelling in favour of propositional knowing and advocacy. Thus, the teller of a traditional tale is more likely to begin by saying, 'Once upon a time there was a king and a queen' rather than 'On the whole, there was royalty'.

In literate societies, the power of the spoken word has largely been displaced by the written word. Walter J. Ong, in his classic study of the development of

language and literacy, explains the psychodynamics of the spoken word for preliterate ancestors. In oral cultures, he says, words are considered to have power; all sound is dynamic, especially oral utterance which comes from inside living beings. In a wonderful example, he points out that while a hunter can experience the presence of even a dead buffalo through all his other senses, if he hears one, then it's alive, and something is definitely going on!

Although similar to each other in many ways, the experience of writing (and reading) a story differs from the experience of telling (and listening to) a story because in the former the relationship between the storyteller and the audience is less immediate than in the latter. There can be no eye contact with the writer and no sense of the writer's physical presence as one reads; the words do not fall upon the ear but linger before the eye, so they can be read and reread at will, whereas the words of the oral storyteller are ephemeral and must command our attention moment by moment.

Whether oral or written, humans tell stories for many reasons: to authenticate their claims to knowledge, to claim their individual and cultural identities, to connect with other people, to influence what others think, to make sense of the world around them, to remember where they have come from, to imagine the future and their part in it and sometimes simply to amuse and entertain.

In all these domains (and countless others), the power of storytelling lies in its exceptional capacity to stimulate both the imagination and the feelings of teller and audience. It does so because, as the cognitive psychologist Jerome Bruner explains, while humans receive information and argument with a logico-rational mindset, through which they can exercise critical judgement, they receive stories with a different mindset, which he calls the narrative mode. He makes a clear distinction between the two, indicating that a good story and a well-formed argument are different natural kinds.

The story is the primary means for humans of attributing significance and meaning to the world and their experience of it. As the anthropologist Hugh Brody explains, this mode of thought developed early in the history of the species (as hunter-gatherers). The logico-rational mind developed later in physiological and social evolution (with the arrival of agriculture and settled communities) and is the primary modality for sorting data, analyzing cause and effect and making critical judgements.

Recent developments in neuroscience support the idea that humans are, in effect, hardwired for storytelling. The synapses in their brains can be observed responding to imagined experiences (through the action of mirror neurons) in much the same way as they do to

similar real-life experiences. The ability to learn from such vicarious experiences is thought to have provided a potential evolutionary advantage to their ancestors in terms of survival, whilst the pleasure to be derived from hearing a good tale might have contributed to social bonding and even to the selection of a mate.

Thinking With Stories

All humans are steeped in stories; human beings are (as an apocryphal story describes it) the ‘featherless storytelling creatures’ of indigenous mythology. Individuals can all benefit from a better understanding of the significance of stories and how they work, but the participative, engaged nature of action research makes storytelling a crucial skill for practitioners, whose praxis is both to understand and to change the stories they study. Furthermore, they must recognize and explore the ways in which they themselves are implicated in those stories and how their own story is changing as a result of their involvement.

Conventional qualitative research methodology invites researchers to distance themselves from the research subjects whose stories they may collect, the content of which can then be analyzed with techniques intended to secure the researcher’s objectivity. In such methodologies, understanding is achieved by thinking *about* the stories that have been told: The logico-rational mode of thought is applied to products of the narrative mode in an attempt to bridge the irreducible differences between them. This kind of textual analysis can render the stories meaningless; at the very least, they become detached from the context of the teller and reduced to data.

The alternative offered by the sociologist Arthur Frank is to learn to think *with* stories. Thinking with stories takes the stories as already complete: They are not treated as data with which to prove or disprove a hypothesis; rather, they become the stimulus for engaged enquiry.

How can this be done in practice? Geoff Mead has argued that people’s understanding of a story is deepened (and its impact on them amplified) when they respond to it with presentational and experiential forms of knowing, keeping it alive and active in their bodies and imaginations *before* bringing their logico-rational minds to bear on it, a process he calls staying close to the story.

Action research is commonly thought of as operating in the realms of the first person, second person and third person (sometimes expressed as ‘for me’, ‘for us’ and ‘for them’). In each of these realms, as articulated by Peter Reason and Hilary Bradbury in the introduction to the *Handbook of Action Research*, storytelling has a significant role to play.

Since first person action research, practice skills and methods address the ability of the researcher to foster an inquiring approach to his or her own life, researchers must explore the way in which they create their sense of self (their self-concept or identity) through storytelling. Conceptualizing the self as a more or less coherent collection of stories is the first step in opening themselves to personal change; most psychotherapeutic approaches are essentially concerned with re-storying the self. Put another way, individuals imagine themselves to be living out a story of some kind, and the kind of story they imagine will shape the way they live their lives.

Since second person action research and practice address researchers’ ability to inquire face-to-face with others into issues of mutual concern, they must be concerned with both how they share their stories with others and how they open themselves to others’ stories, as well as how they co-create stories in the course of their mutual inquiry. Here, they directly encounter issues of power and voice, of whose story counts the most and of how to listen deeply to stories that are different from (even antithetical to) their own. Turn-taking structures such as story circles are particularly useful to democratize the storytelling process and to open up communicative spaces in which one can go beyond superficial exchanges of opinion.

And since third person research and practice aim to create a wider community of inquiry involving persons who, because they cannot be known to each other face-to-face, have an impersonal quality, researchers might seek to expose and disrupt the hegemonic stories that unconsciously govern their behaviours in ways that maintain systems of power and authority. They can do this by telling (or helping others tell) stories from countervailing stances. There are many examples of this type of intervention: stories of people with disabilities and their carers, stories from ethnic minorities and indigenous communities, stories from the transition town movement, stories from the front line in Afghanistan, stories of religious dissenters, stories told on behalf of animals and the more-than-human world. Coming out of what Jürgen Habermas called the life-world rather than the system world, such stories testify to other realities and challenge existing regimes of truth by offering alternative discourses.

Storytelling, as Walter Benjamin told us in 1936, has a moral dimension. The stories people tell are fateful, and in this postmodern (perhaps hyper-modern) age, the importance of storytelling is increasingly recognized. New social media provide platforms for an unprecedented exchange of personal stories; the art of traditional storytelling is undergoing a widespread revival; environmental activists call for a rejuvenation of oral culture as an ecological imperative.

When, in 1979, Jean-François Lyotard declared the end of the grand narrative of modernism, it signalled not the end of storytelling but the legitimization of a multiplicity of stories told from many standpoints: a world in which little can be taken for granted and in which the grip of hegemonic stories has been loosened. Storytellers and action researchers can take heart from Arthur Frank's conclusion that the moral genius of storytelling is that each teller and listener enters the space of the story for the other. Telling stories in postmodern times, and perhaps in all times, attempts to change one's own life by affecting the lives of others.

the organization wants to be, in other words, strategic direction. Step 3 is to plan effectively to get there, in other words, to implement a plan based on strategic decisions. Step 4 is to monitor the progress of the plan implementation. These four stages are desirable to complete the full cycle of a strategic plan.

Relevance for the Not-for-Profit Sector

The resources of the non-profit organizations are primarily provided by individual donors, the institution or the government. Being the recipient of public funds, there is a social and moral pressure on the organization to demonstrate outputs and change. Measurement of changes in the life of the poor and disadvantaged sections of the society due to interventions of the organization has always been a challenge. Therefore, the public nature of the grants provided to non-profit organizations demands greater accountability and the most effective use of the resources. Strategic planning becomes an important exercise to be effective in attainment of impact along with efficient utilization of resources.

Dimensions of Strategic Planning

The strategic planning involves initial agreement of a governing board. (Non-profit organizations are registered under various acts as per the laws of the land. The governing structure is defined differently in different countries or by different organizations). In other words, the apex decision-making system of the organization initiates the process. It begins by identifying a steering group or team within the organization. Most likely, the chief executive of the organization leads the process. The governing board provides the team a mandate for the strategic planning. The principles of participation of the primary stakeholders and the scope of the strategic planning are defined by the board to determine the time frame and required resources. The board or the senior management may decide to engage an external facilitator to ask relevant questions and help the team work out strategic choices. The process of strategic planning involves the following:

- Revisiting the vision and mission of the organization and building a shared understanding is the first step after undertaking an organizational assessment through internal reflection or by an external evaluation. The vision is a larger world view of the society which provides values for the organization. The mission statement draws a line as to what the organization will do effectively and what it will not do or should not undertake.
- The SWOT (strength, weakness, opportunity and threat) analysis provides a realistic assessment to

STRATEGIC PLANNING

Strategic planning determines the focus and direction of the organization for attaining the mission within the given external environment, making the best use of the available resources within the given time frame. A strategic plan can be prepared for 1 year or longer depending on the size, complexity of interventions and age of the organization. Michael Wilkinson defines strategic planning as a four-step process. Step 1 is to understand where the organization is now, which is also known as situation assessment. Step 2 is to determine where

determine how far the organization can stretch to expand and where it should focus for quality impact within the current opportunities and threats in the environment. There are various other methods of identifying the organizational capacities and scanning the environment, for example, PEST (political, economic, social and technological) analysis and the Appreciative Inquiry method.

- The strategic options for the organization become easier with a detailed and appropriate SWOT analysis. The strategic choices are identified in areas such as geographical expansion versus consolidation, thematic diversification versus deepening engagement in existing thematic areas, different forms of team organization and so on. Each of the options has certain advantages and disadvantages. The organization has to weigh the best option to make choices. Making well-thought-out choices is critical in strategic planning. Therefore, it becomes different from regular activity or programme planning. The strategic choices are followed by detailed resource planning. It means that the required financial resources and human resources for attaining the outcomes are undertaken after the strategies and broad activities are determined as part of the strategic plan.

- The strategic plan needs to be endorsed by the governing board, and it should be widely shared with the stakeholders so that they know about the shifts and change in the goalpost, if any, for attaining different sets of results. The plan should be regularly reviewed and monitored so that the set goals and mission are achieved with efficient use of the organizational resources.

Knowledge Generation and Action Research

The success of the strategic plan depends on the level of engagement of various stakeholders in the process of preparation. The governing board needs to be involved to revisit the existing vision and mission. The board may decide to revise the vision or mission of the organization in the light of the changing environment. A participatory evaluation of the organization or any specific programmes can be a starting point for the involvement of data generation in the performance of the organization and the programme. Knowledge generation by the primary stakeholders of the organization, in other words, communities and staff, along with other stakeholders such as donors, government officials and other interested persons or agencies initiates the process of self-reflection within the organization. Participatory research leads to the understanding of strengths, weaknesses, opportunities and threats from the lens of the constituencies the organization serves.

A workshop of the primary stakeholders leads to determining actions and strategies. The board members provide an oversight function to dispassionately advise the most effective possible choices. The team concerned with attaining a specific result will detail out strategies for attaining the outcomes. Such organizations build a culture of participatory knowledge generation, where the constituencies served and the 'not powerful' staff within the organization are invited for reflection. Their participation and contributions are respected. The data generated is used in the process of strategic planning and action. Such organizations become learning organizations and remain relevant in a dynamic and changing external environment.

STRENGTHS-BASED APPROACH

Strengths-based theory and practice incorporate a multidisciplinary approach derived from a range of sources including social change theory, motivation theory and positive psychology. The basic tenet of any strengths-based approach (theory and practice) is that every individual, every group and every organization has strengths. Identifying these assets and using them as a starting point for research or practice enables researchers to frame their work within a positive paradigm and build upon the available strengths.

The approach was developed as a counterpoint to the more traditional deficit approach wherein professionals, as experts, would observe their subjects and identify their deficits so as to then intervene, address the deficit and solve the problem. This deficit approach, however, could undermine participant confidence and sense of self-esteem and self-efficacy.

Conversely, a strengths-based approach can enhance participants' sense of self as they generate strategies and solutions for themselves and their context. The approach emerged from the fields of social work and family and community services, and its application continues to expand, for example, to health and educational contexts.

Strengths-based theory and practice do not expect the researcher to ignore deficits and problems but to adopt a perspective that incorporates a new balance when researching and working with individuals, groups and organizations. Deficiencies are not emphasized. While one can acknowledge that a range of challenges exists, at the same time one can use a strengths-based approach to work through any challenges *with* the individual, group or organization. Researchers will vary in the degree to which they apply this theory and practice. Contemporary contributors to this field are Wayne McCashen and Dennis Saleebey.

A strong alignment between a strengths-based approach and action research make it an appropriate choice for the action researcher and practitioner. This entry starts with an overview of the alignment between the approach and action research, followed by the strategies available to support this option for research. The alignment and strategies for integration of practice conclude the entry.

The Nexus Between Strengths-Based Theory and Practice and Action Research

The central tenet of strengths-based theory and practice is analogous with that of action research: All stakeholders in a project or activity are participants in a process of enquiry searching for the best answers and solutions while developing new knowledge. To achieve this critical nexus, the strengths-based approach requires a focus upon, and uses as a starting point, the identifiable strengths of these participants. Both the strengths-based approach and action research share an emphasis on action as a goal and on achieving change. Given that reflective practice is valued and inherent to both, this change may be transformative.

A strengths-based approach can inform the theory, research and practice of action researchers as they progress through the stages of the action research cycle. Several components of the theorizing process of the action researcher will be influenced when a strengths-based approach is integrated into research. Initially, the basic assumptions underpinning the researcher's theorizing will incorporate three key principles: (1) that all individuals, groups and organizations have strengths; (2) that researchers work collaboratively with individuals, groups and organizations and (3) that an outcome of the research process is action that results in change.

Contributing to this theory building, key concepts related to the research will acknowledge, connect and build these assumptions into a coherent theory adopted by researchers to frame and inform their work.

Each component of the simplified action research cycle of plan, act, observe and reflect can be informed by a strengths-based approach.

Plan

The planning phase requires action researchers to identify research strengths as areas for enquiry, drawing on existing resources. Action research plans should be developed through a process of negotiation and founded upon a strengths perspective. This can be achieved by incorporating and extending upon research practices that team members have already demonstrated as successful. Key research questions need to be framed with a strengths perspective, and this approach then cascades to the role of questioning throughout the project. Thoughtful, even reflective, questions that empower all participants are aligned with this approach, for example, asking research participants and colleagues, 'How do you feel?' or 'What would you suggest?'

When a strengths perspective is overtly and publicly stated in research plans and grant applications, then researchers can feel empowered and validated in using the approach as a legitimate research strategy. In turn, they may also be more confident as they feel safe and sanctioned to model this approach with all research team members and participants with whom they interact.

Act

Throughout the acting phase, both action researchers and participants enact a strengths-based approach. This includes identifying, acknowledging and developing strengths. Data collection is more than a process of gathering information. Researchers need to refine their questioning skills, remaining cognizant that participants have the answers and that there is no need to provide them.

Observe

The observation phase requires action researchers who are using strengths-based theory to figuratively wear lenses that focus on the positive contributions that are being demonstrated. Emphasis is placed on observing and identifying the strengths of participants within the context of the research process, while also acknowledging areas for ongoing development. Strengths are noted and may perform the role of critical, or noteworthy, incidents that can prompt and focus reflection in the next phase.

Reflect

Reflection is the defining phase of the action research cycle. A strengths-based approach espouses that researchers evaluate and review their actions and processes at each step of the research project. This allows the acknowledgement of achievements and aligns with the reflection phase of the action research cycle, a practice that is repeated with each iteration of the action research cycle. Upon reflection, constructive evaluative feedback is provided. The resource of dedicated time needs to be provided to make possible the reflective process.

Strategies for Integrating a Strengths-Based Approach Into Action Research

Integrating a strengths-based approach into research requires a move from doing research ‘on’ people to one of research ‘with’ colleagues and participants. With its close alignment to action research, there is a range of strategies that can be considered to enhance the enactment of strengths-based practice with research projects, teams and participants. These strategies include the following:

- When first forming an action research project team, select and invite the team members based on their strengths and on their potential for living a strengths-based approach. Authentic case study scenarios may be presented to potential team members that require a response, which can then be evaluated for its affinity with a strengths-based approach.
- Select qualified colleagues who enhance the success of action research and support the co-development of strengths in colleagues.
- Actively educate colleagues in both strengths-based theory and practice, and provide access to training and Action Learning options.
- Encourage colleagues, such as research team members, workplace partners and research participants, to share their strengths by encouraging them to provide formative and ongoing feedback, for example, through a feedback box, wiki or blog.
- Provide colleagues with regular opportunities for input into research activities, for example, by co-generating an agenda or negotiating a research action plan.
- Provide regular opportunities for colleagues to meet informally over a staff or project team lunch or more formally through structured discussion and reflection times.
- Develop regular and effective communication, whether it is face-to-face, through printed

media such as newsletters, or electronically through different forms of social media.

- Share and disseminate information on strengths-based theory and practice with colleagues, and encourage them, through networking, to do the same.
- Model the approach in your relationships with colleagues, an important aspect of which is avoiding stereotyping and judging colleagues or research participants.
- Use a constructive approach for all feedback to support a strengths-based approach—for example, always start and finish with an acknowledgement of a strength.

In project teams, a strengths-based approach will clarify what is possible, allowing participants to share leadership while progressing towards research goals. Leadership thus becomes fluid, determined by the strengths that each team member contributes to the research project. Members take turns to lead the research as they draw on their strengths at appropriate developmental phases of the research project. This form of leadership is aligned conceptually with ‘distributed leadership’, where leadership is not limited to a traditional hierarchical or formal positional approach but is distributed across all levels of a team or organization. Acknowledging that all individuals have strengths extends to the assumption that all individuals can lead.

Active listening and providing affirmation are important strategies in a strengths-based approach. This means extending an affirmation to the research contributions of colleagues and acknowledging contributions, for example, with thank you notes or e-mails. It involves reinforcing and acknowledging prior learning and experience as a strength. It means allowing colleagues to have some autonomy but also balancing this autonomy with clear boundaries, monitoring through the use of mentoring and being available, consistent, and respectful.

At the commencement of a research project, reasonable expectations need to be established, so that individual strengths are used, developed and extended. However, if things go wrong, avoid apportioning blame. A strengths-based approach aims at shared responsibility founded on collegiality. Overtly acknowledge challenges and use reflective practice to develop strategies to address these challenges. Action research provides a researcher with the iterative cycles to test strategies and to amend plans in response to challenges. Incorporating a philosophy of organizational change into research overtly acknowledges that change is a part of both action research and a strengths-based approach.

At every stage of action research, it is necessary to collaboratively debrief with reflective colleagues. Always aim to end any action research process, whether

it is a meeting, interview or evaluation, on a positive note. When writing up and disseminating research results and findings, ensure that a language of strengths is used for reports, journal articles and all publications.

Strengths-Based Practice

A strengths-based practitioner will adopt a variety of strategies and processes when interacting with individuals, groups or organizations. First and foremost, the practitioner, like the researcher, will encourage individuals to draw upon their strengths to make decisions and devise individualized strategies or action plans to address any challenges with which they are presented. For example, a practitioner working with new parents will assume that the infant's parents know the baby best and with time and support can devise solutions to many of the challenges they may face.

The practitioner adopts the role of a supporter, providing a secure foundation upon which the individual or group can develop their strengths. The practitioner does not adopt the role of an authority or expert but one of a peer who is there to support the individual or group as they work through the decision-making process to find solutions to their challenges. A mother with young children experiencing domestic violence may be empowered to leave the violent relationship when she is supported to identify that her love for her children is a strength and a motivator for change.

The practitioner may provide and build links for the individual or group with opportunities to learn and develop. For example, a practitioner working with a homeless person may provide a safe and supportive environment for the individual to explore new accommodation. The individual can articulate the steps he or she has already followed, and after affirming this progress, the practitioner can provide additional links to aligned services and support.

Strengths-based practitioners benefit from a holistic or ecological approach to their work and research. They acknowledge and collaborate across disciplines and organizations, drawing upon the strengths of each to provide for the needs of the individuals and groups with which they interact.

Strategies for Integrating a Strengths-Based Approach Into Practice

Strengths-based practice is an effective approach as it brings about change. This approach can result in a spillover effect, for as strengths are identified and shared, others' perspectives are reframed towards a more positive paradigm. Focusing on strengths can result in researcher, practitioner and participant achieving a more positive sense of efficacy.

It may be challenging for individuals and groups to be aware of their strengths not having thought about them before; therefore, the researcher or practitioner can play a significant role in facilitating an awareness of strengths and validating the role of individuals and groups. Ownership and partnership are the foci of any strategy used by practitioners. Envisioning a successful outcome can be an effective strategy for the practitioner and participants.

Aligned with this approach is the use of positive reinforcement. Practitioners reinforce positive strengths with verbal and non-verbal praise as appropriate to the participants and the context.

A strengths-based approach requires practitioners to draw upon professional knowledge. As this approach is applied to research or professional practice, the experience develops new knowledge. This knowledge development, as with action research, cannot be fully predetermined or controlled. An important strategy is to acknowledge and allow for flexibility in professional practice that adapts and adjusts to contextual needs, for it can be during unplanned, informal moments that new knowledge is created. In addition to being flexible, the practitioner needs to accept that change takes time and is incremental, with small changes leading to bigger changes. Strengths-based theory and practice offer researchers and practitioners alike a multidisciplinary, collaborative and positive paradigm for change, with the potential to further encourage growth in the capacity of all participants.

SUBALTERN STUDIES

'Subaltern studies' refers to the study of social groups excluded from dominant power structures, be these (neo)colonial, socio-economic, patriarchal, linguistic, cultural and/or racial. When people lack voice, when they are barred from systems of political or cultural representation, they are called subaltern; their subalternity is the consequence of their limited access to structures of authority. Subaltern studies investigate both these structures of authority and the consequent conditions of subordination experienced by marginalized groups.

The term *subaltern* has military origins, referring to a junior or subordinate officer. The Italian political philosopher and activist Antonio Gramsci made the term famous, reportedly using it as a synonym for 'working class' or 'proletariat' to avert censorship of his writings by prison authorities during his lengthy incarceration. But it is the Subaltern Studies Group, made up of historians of South Asia, who have made the term central to their work, influencing not just the contemporary study of historiography but also their understanding of the politics of representation. Their work has been taken up by, and has important implications for, several fields of study, including cultural studies, post-colonialism, feminist politics and, indeed, action research. Moreover, while once dominated by South Asianist researchers (e.g. Ranajit Guha, Dipesh Chakrabarty, Partha Chatterjee, Gyan Prakash and Gayatri Chakravorty Spivak), the study of subalternity is now central to the work of many Latino or Latin American post-colonial scholars (e.g. Gloria Anzaldúa, Édouard Glissant, John Beverley and Walter D. Mignolo).

The Difficult Task of Investigating Subalternity

Since their establishment in the 1980s, the intellectual purpose of the Subaltern Studies Group has been to 'write history from below': They have been critical of mainstream historiography (e.g. colonial, nationalist, Marxist), which they say has tended to represent history from the point of view of the colonizers or social and economic elites, thus discounting the agency of colonized and subaltern groups (e.g. subsistence farmers, informal-sector workers, indigenous communities, marginalized women, slum dwellers and racialized minorities). Their aim, therefore, has been to try to rectify what they see as the elitist bias of much academic research.

In the early writings of the group, edited by the historian Guha, the tendency was to valorize subaltern agency by trying to represent it as independent and autonomous of elite politics. But this task proved increasingly difficult. Partly, it was a conceptual problem, since by

definition subalternity meant subordination to a dominant power, implying the impossibility of autonomy. Partly, it was an evidentiary problem, as documents written by subaltern groups (e.g. worker diaries, peasant testimonials) during colonial times proved difficult, if not impossible, to find. And partly, it was a political problem, with the discovery that so many subaltern acts of rebellion against the colonizer had failed. Many members of the group thus came to the realization that not only were subaltern attempts at political change often temporary and unsuccessful but the very project of investigating independent subaltern agency was doomed; far from ignoring or discounting elite powers, the project of retrieving the subaltern 'voice' could in fact only happen in relation to the dominant.

Can the Subaltern Speak?

Spivak's groundbreaking article 'Can the Subaltern Speak?' pushes this problematization of the recovery of the subaltern voice even further. Focusing on the gendered subaltern, Spivak contends, in fact, that the subaltern *cannot* speak—not because the woman does not have a voice or will not act but because she is not given a subject-position from which to speak or act. In other words, for Spivak, elite discourses are so powerful that they ignore, filter out and are deaf to the subaltern, so much so that even when the subaltern does speak, she is not heard.

Spivak's important point is that the subaltern voice is always mediated by dominant systems of representation. And her argument has at least three related implications for researchers:

- We have no unmediated access to subalternity: Because we always work from within dominant epistemic systems, we cannot retrieve any 'pure' or 'authentic' subaltern voice.
- We cannot claim neutrality or objectivity in our research on or encounters with the subaltern: We always bring our personal, professional, institutional, socio-economic and geopolitical biases into our work—be they deadlines, budgetary constraints, ideological prejudices or gender and class positioning.
- To the extent that our representations of the subaltern say more about us than about the subaltern, we *produce* the subaltern and, in fact, we may well end up reinforcing their subalternity. When our representations reflect our own image and desires, then not only are we unable to encounter subalterns on their own terms, but in so doing, we are merely reproducing our dominant epistemic structures. Our representations run the risk of

appropriating the subaltern for our own purposes, denigrating, orientaling or, indeed, romanticizing them to suit this or that personal or political objective of ours.

Hearing the Subaltern

How, then, do researchers encounter the subaltern, even as they are immersed in dominant systems of power and representation? How might they really hear what subalterns have to say or, indeed, learn from them? Far from retreating from these difficult tasks, the Subaltern Studies Group has been adamant that not only are the tasks worth doing but also these decolonizing gestures must be done with great care and responsibility. Even though the very recovery of the subaltern voice risks its erasure, it is crucial to record this erasure so as both to valorize the space of 'difference' of the subaltern and to critique the domination of imperial, socio-economic, epistemic and patriarchic discourses.

Acknowledging the researcher's complicity in and contamination by the dominant power structures helps researchers and investigators contextualize their claims, reducing the risk of personal arrogance or geo-institutional imperialism. In this regard, the Latin American post-colonial critics Anzaldúa, Mignolo and Glissant speak of 'border thinking' to reveal the hybridity and diversity within seemingly unified dominant power structures. Border thinking not only helps unsettle 'core' foundations of the Western canon but also enables researchers to see how 'peripheral' (e.g. Native American or Latino/a American) ideas and practices have shaped the 'core' (e.g. global actors such as the USA). Glissant coins the term *diversality* to refer to opening up new imaginaries and initiating meaningful intercultural exchange: Diversality implies coming to terms with the difference and what he calls the 'turbulence' of the subaltern while simultaneously unlearning dominant systems of knowledge and representation.

SUBALTERNITY

The notion of subalternity is associated with the subaltern, in other words marginalized individuals or groups who are disenfranchised because they are not part of the hegemonic power structure of a society or colony. It means belonging to or being the subaltern. The word *subaltern* has a long history of usage. The perspective of the marginalized, or the study of cultures 'from below', has been part of colonial histories and literature from the eighteenth century onwards. The term as it has come to be used today, however, has its origins in Gramsci's writings on the proletariat or working-class struggles. The concept was appropriated in a particular way in post-colonial theory in India by Ranajit Guha, who was highly influential in the development of subaltern studies, offering a new site for scholars to explore studies of nationalism, societies, histories and cultures from below. Gayatri Chakravorty Spivak, in 1988, broadly referred to subalternity as the interrogation of a voice that could not be heard since it was structurally written out of the imperialist or colonial narrative. While confined originally to post-colonial theory, cultural theory, literary theory, cultural anthropology and nationalism, the notion of subalternity has influenced the nature of research in many other domains of study and research, such as policy studies, developmental studies and sociolinguistics. It is included here since a consideration of subalternity in action research contexts has the potential not only to ensure a critical site for inclusion of marginal perspectives within scholarship but also to give voice and discursive space to individuals and communities that we partner in collaborative research and in the production of co-generative knowledge.

In policy studies, for example, the notion of subalternity may need to be included in the interpretation of data collected from individuals and groups, since it denotes in a particular way the social actors who become the crucial agency that affects and shapes the way a certain social policy is implemented.

In sociolinguistics, and in the study of language policies in multilingual contexts in particular, perspectives on how macro language policies are being implemented increasingly include subalternity as a research variable to gauge the efficacy of implementation in local contexts. A recent sociolinguistic study by Pol Cuvelier, Du Plessis, Meeuwis, Vanderkerckhove and Webb (2010), for example, provided a forum for

scholars in different countries to examine language policy implementation in multilingual contexts from the perspective of the subaltern; that is, those who rather than submissively implement policy, modify it, renegotiate it and re(de)fine in on the ground.

The Subaltern as Participant in Action Research

Action research involving reflection on the implementation of any given policy in organizations or communities can include subalternity in the creation of change and collaborative learning. The inclusion of a consideration of subalternity may become important in ensuring a truthful, dialogic transaction between researcher(s) and participant(s). In other words, for sociocultural, socio-economic or ideological reasons, the participant, while participating in the action research process and co-generating knowledge, might, nonetheless, see herself or himself as residing or located at the margins of the research process and power structure. Thus, the participant might need to be given space to speak, to have voice outside the hegemony of any research approach, however inclusive and collaborative it might aim to be. Rather than being the passive collaborator in action research, the participant as social actor can appropriate the research agenda, steer it in novel and unforeseen directions and demonstrate agency and ownership. A careful consideration of subalternity in action research, therefore, has the potential to ensure a more dialectic, truthful and transformative process of interaction and exchange between researcher(s) and participant(s). This means that once given the site to 'speak', as in Spivak's original conceptualization, truth is co-constructed by researcher(s) and participant(s); subaltern agency can become an active and powerful social agency of change exercising power and influence within the constraints imposed by organizational structures or research structures.

The Local and the Subaltern

For the researcher and the participant, it is worth considering that the subaltern is often best defined and understood in terms of and in relation to the local space or local site which they physically, emotionally and spiritually inhabit. Suresh Canagarajah has proposed that the notion of the local is often short-changed in the discourses on globalization, reminding us that the local is not of secondary importance or of a subsidiary status to the dominant discourses of the powerful community, where the global is applied or contextualized to the local.

This means that we may need to re-examine our disciplines and approaches to research to orientate to social relations from a radically different perspective. Thus, research with co-participants must include not

only their interpretations of the research questions and agenda but also their negotiations and resistances in the local site they inhabit. This interpretation helps the researcher to understand the realistic scope of action available to individuals and the locality that shapes their experience.

Subalternity, therefore, can be closely related to action research. Firstly, subalternity in action research contexts has the potential to include marginal perspectives within scholarship. Secondly, it allows the participant who may see himself or herself as belonging outside the research process, or marginal to it, to participate not only in a site where he or she can have voice but in a place where he or she can have agency and steer the research process in a new or in an unforeseen way.

SUPERVISING ACTION RESEARCH THESES AND DISSERTATIONS

Supervising action research theses and dissertations means helping students understand action research

methodology in theory and practice, specifically how to (1) plan, implement and evaluate an action research project of significance in a particular context and with a group of people who are as passionate about solving the issue or problem of concern as the student-researchers themselves; (2) collect, record, analyze and interpret qualitative data relevant to answering the research question and (3) write a concise thesis or dissertation within a given timeline.

The most effective way to supervise action research theses is to practise and model action research philosophy and values with students by using a collaborative, participatory approach to supervision rather than the single-supervisor model based on a hierarchical relationship. This requires the supervisors to be collaborative, reflective, innovative and creative in their supervisory practice and in forming Action Learning ‘sets’ (groups) of students as action researchers for mutual support.

Supervising action research theses is a topic of urgent importance to students, supervisors and institutions in the present climate, when global problems through economic crisis, climate change and so forth spark ever-increasing interest in action research as a methodology for addressing important, totally new and complex organizational, community and social issues. Students’ lack of knowledge about the action research paradigm, methodology, processes and project management may lead to poor-quality research and writing and/or delay in completion time or non-completion—with all kinds of implications. For example, floundering students often suffer from personal/psychological/health problems and fail to maximize their learning opportunities. And because some governments no longer fund students who delay or fail to complete their theses, institutions miss out on the necessary funds for resources, and consequently, supervisors must take on a higher workload along with cost to their academic reputation from supervision failure. Therefore, we need (a) useful resources for supervisors and students; (b) a supervisory praxis that mirrors action research culture, values and strategies and (c) effective, alternative structures to replace or improve the traditional single-supervisor model.

Useful Resources

Books such as Gina Wisker’s *The Good Supervisor* and Kathryn Herr and Gary Anderson’s *The Action Research Dissertation* and guides such as Bob Dick’s *Action Research Theses* and *AREOL (Action Research and Evaluation Online)* are of paramount importance. This is especially so when applying and teaching qualitative research and action research because these methodologies are relatively new and are not taught or

understood to the same extent as traditional, quantitative research and statistics.

Supervising action research theses can be more (and also less) difficult and time-consuming than supervising traditional research theses. As just mentioned, it is more difficult because the methodology is relatively new, and supervisors often struggle themselves when using and especially when teaching it. Therefore, postgraduate research students should be required to complete a course on action research (including qualitative research) before enrolling in a higher degree programme. If that is not possible, Bob Dick’s free online course on *AREOL* is highly recommended, especially the assignments, which may be assessed, examined and even accredited by supervisors and action research specialists in a university.

Action Research Culture

Action research has its own distinctive research culture formed by action researchers’ beliefs, values or *Weltanschauungen* (world views). Just as culture is the expression of the usually unacknowledged, often unquestioned ways in which we think, speak and live, similarly a research paradigm (as defined by the renowned science philosopher Thomas Kuhn) comprises the full constellation of beliefs, values and techniques that members of a community of scholars share.

An action research culture or paradigm is normally known to be inclusive, friendly, open, sharing, collaborative, empowering, democratic, critically reflective, emancipatory and enjoyable. Action research has been proven to be an effective method for (1) conducting research that is practical, useful and relevant to professional practice and organizational or community learning and (2) developing people’s ‘soft’ skills, competencies and other attributes required by employees, group members and leaders in ‘learning organizations’ in the twenty-first century. The five disciplines of a learning organization (as defined by Peter Senge, the creator, theorist and practitioner of this concept) are also the aspirations of action researchers, namely, personal mastery, mental models, a shared vision, team learning and systems thinking. Systems thinking means that all members understand the whole organization’s culture, structure and processes, rather than only parts of these, and that collaboration and team learning are essential for synergy, meaning that the collaborative team results are more effective and richer than the sum of the individual contributions.

Supervising action research theses can be made easier if students work in groups instead of individually and collaboratively instead of competitively. However, supervisors need to have or obtain the knowledge and process facilitation skills to work with groups

effectively and develop lifelong Action Learning for action research students so that they can live and work in the action research culture.

Group Supervision

A new structure is proposed here for an action research methodology model for postgraduate supervision that involves candidates in providing guidance and help to each other and sharing resources in a group setting. Supervisory groups comprising both students and supervisors can usefully supplement the traditional structures that involve only faculty (e.g. the single supervisor, joint supervisors or supervisory committees). While in the traditional structure, supervisors are usually content to be experts in their discipline, while supervisors of action research theses need to be interdisciplinary problem-solvers and knowledgeable in action research methodology. This can be a problem for supervisors who are either just beginning their own work in action research or coming from a different paradigm and methodology. These supervisors need to learn, and that is the advantage of an action research culture. It allows you to admit your weaknesses as well as your strengths and learn with and from your colleagues and students. For example, here are two scenarios.

First, form an Action Learning set of three to six students who can work with or without a supervisor as self-directed, autonomous learners. In the beginning, facilitate the process of relationship and team building and introduce ground rules, the use of a reflection diary and a SWOT (strengths, weaknesses, opportunity and threats) analysis. Students must understand the need, and make a commitment, to attend regular (weekly or fortnightly) set meetings to share access to faculty supervisors and other resources and help each other in completing their research and thesis on time. Once this arrangement is in place, each meeting has an agreed agenda, starting with reflections on the previous meeting and on subsequent actions, followed by some focused input from a faculty member (and increasingly from a student later), with subsequent discussion and questions. At the end of each meeting, members in turn reflect on what went well for them, what did not and why or why not. Then, they agree on the agenda for the next meeting, with a new focal topic and presenter. The advantage of covering one key issue/topic (or more) per session is that supervisors can be sure that in the end all students have been exposed to all the essential knowledge and skills necessary for an action research thesis. Another advantage is that supervisors need to provide the necessary information only once instead of multiple times. In the traditional structure, supervisors do not always remember what they taught or discussed with individual students, which can often lead to misunderstandings

and misguided expectations. The reason for limiting an Action Learning set to six members is that this is the maximum size for a leaderless group (without a chairperson). And with more experience, the group can meet without a supervisor. For example, they may invite guests who have successfully completed their higher degrees and can talk about their positive and negative experiences and their learning. Students can also share information and resources that they have found useful and read and comment on one another's first drafts of proposals and chapters before submitting their work to their supervisor. Any reciprocal input into their research projects may reduce supervisors' workload.

The second scenario of group supervision is a larger programme with several Action Learning sets. Think of other colleagues in your university, or in other institutions in your region, who supervise action research theses. Invite them and their students for a 'think tank' or an initial workshop to discuss mutual interests and a possible joint programme with a series of workshops on general issues of action research, thesis writing and supervision. These workshops can be facilitated in turn by faculty supervisors (and possibly by students later) to discuss key problem areas among students and supervisors, such as staff/student expectations, the role of the supervisor, thesis requirements and standards, defining the central/focal research problem or question and identifying its significance and methodology, proposal writing, mind maps and model building, planning and writing the first draft with clear concepts and structure (in contrast to the fine-tuned and precise final draft), the use of a bibliographical database and so on. These interdisciplinary, intra- or inter-university workshops increase networking and support for both supervisors and students and reduce supervisors' time spent with individual students without cost to the student. It does not matter that students' thesis topics are unrelated and in different disciplines—on the contrary, students learn to answer questions in simple English instead of jargon—but what they all have in common is an interest in action research and how to complete a thesis successfully and in minimum time.

Advantages

The advantages of including candidates in group supervision are clear. Students continue to be actively involved in critical thinking through group reflection and interaction, they have input into the content and decision-making of the workshop programme, they share ideas and resources and they maintain high motivation through group support. These processes are true to the action research culture/paradigm, especially collaboration and the cycles of planning, acting, observing and reflecting—learning, researching and supervising through action and for action.

Limitations

Whilst these group supervisory sessions with student involvement are very useful at the beginning of candidature and for developing methodology, there comes a time when students need to work on their own particular content and problem in depth and face-to-face or electronically with their supervisor(s). Students' needs change from group to individual supervision.

Another limitation may be that students are at different levels of understanding of action research and of one another's disciplines. Therefore, the workshops have to cater to all student needs. More advanced students benefit from smaller subgroups of two to four (rather than the large group) in order to have more specialized discussion of their thesis progress and of tabled action research case studies and completed theses as examples/models. In conclusion, larger, cross-discipline group meetings with one or several supervisors can work well at the early stages of the research process, but these group meetings soon need to be supplemented by topic- or problem-specific subgroups with their own supervisor.

Conclusion

Supervision of action research theses and dissertations requires the same supervision capabilities, strategies and skills as for other theses, but it also requires knowledge of action research methodology, a relatively new and constantly emerging field. In this sense, some supervisors may find it more difficult, but it can be made easier if the single-supervisor model is supplemented by group supervision with candidates' involvement in small Action Learning sets of up to six members (Scenario 1) and/or larger workshop programmes with several faculty supervisors sharing the tasks and workload of research guidance (Scenario 2). Both group structures constitute a support system for supervisors and postgraduate students, reduce students' intellectual isolation, improve their performance and productivity and may lead to lower attrition rates. The importance of group support in boosting students' morale, self-confidence and learning has not drawn the attention it deserves as a means of reducing high attrition and low or late completion rates among postgraduate students. Through participating in collaborative supervisor-candidate sets and contributing to the workshop programme, supervisors can create a more co-operative and open environment for learning and research that is appropriate for the purpose of action research, with intellectual enrichment for supervisor as well as student.

SUSTAINABILITY

Although there are many definitions for sustainability, most frequently it is described as the *state* that results from the *process* of sustainable development. The most generally accepted definition of sustainable

development appeared in the 1987 Brundtland Report, published by the World Commission on Environment and Development, where a sustainable form of development was described as one that meets the needs of the present without compromising the ability of future generations to meet their own needs. Thus, this definition recognizes that development need not be inconsistent with sustainability. The key implications for sustainable development and for the associated *state of sustainability* are the twin principles of intergenerational and intra-generational equity. Intergenerational equity refers to preserving capital or resources for future generations, and intra-generational equity refers to fair access to capital or resources for current generations. Decision-making that accords with sustainability requirements considers and seeks to balance short- and long-term human, economic, environmental and social needs. Such decision-making should also seek to adopt a precautionary approach—allowing that if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.

Current sustainability areas of local, national and international concern include combating global warming, managing ecological support systems, conserving natural resources (e.g. water, soil, air, species and ecosystem biodiversity), supporting a cyclical economy and ensuring an equitable society in terms of quality of life. The 1992 Declaration of the United Nations Conference on Environment and Development (the Rio Declaration) in adopting the concepts outlined in the Brundtland Report also embraced the principles of the earlier (1992) Dublin Conference: that ascertaining the divergent human demands with regard to natural resources, and how they change, was as critical to science-based decision-making as an understanding of ecological science. This approach pointed to a role for action research as a tool for engaging stakeholders in complex decision-making. This entry provides a brief explanation of the increasing importance of sustainability to communities and in policy development and organizational decision-making. The entry also discusses some of the key strategies, many based on action research and Action Learning principles, being adopted by institutions and organizations of all types in order to support a more sustainable future.

Adaptive Management and Sustainability

In the 1970s, North American scientists, confronted by issues of complexity, uncertainty and risk in seeking to sustainably manage bounded ecosystems, developed the concept of adaptive management. As expounded by 'Buzz' Holling and others, adaptive management

in its simplest form is a common-sense application of a recursive approach to the scientific method of controlled experimentation, advocating that implementation of management policies is primarily an experiential learning experience. Adaptive management explicitly recognizes the need for management decisions to consider economic, social and environmental values in an integrated and decentralized fashion, the need for the presence of diverse stakeholders in environmental management issues and the inherent uncertainty of environmental processes. In these concepts, one can see the genesis of the Dublin Conference principles, which, following the Rio Declaration, were embodied in the Rio implementation plan titled *Agenda 21*.

Since the 1970s, the principles of applying a process that involves a cycle of 'plan-do-review-re-plan' have been recognized as something that can be applied to more extensive ecosystems than those first considered. Adaptive management focused attention on the need to consider a broader range of contexts, levels and scales for policy formulation and decision-making where complexity, uncertainty and risk are involved, including in political, governmental, business and other social spheres. More recent formulations perceive the adaptive approach as relevant within the context of participatory (or adaptive) governance.

The need for participatory approaches to awareness raising and implementation of sustainability concepts relates to the multiple interpretations of what equitable access to resources or capital means for now and for the future. For example, capital may be thought of in terms of natural, economic, built, cultural or social capital or as human skills and capabilities. Wider interpretations of sustainability are classified as either strong or weak according to whether all forms of capital are maintained intact independent of one another. Strong sustainability requires that each form of capital is kept constant. When applied to the organization, strong interpretations therefore assume that social, environmental and economic objectives must be addressed simultaneously if any one of these objectives is to be of value. Hence, the adoption of a position on intergenerational equity which aims to preserve economic and built, but not natural, capital is described as 'weak sustainability', while a 'strong' or 'deep green' position argues from the perspective that nature has intrinsic value and therefore cannot be compensated for with economic or built capital. Coupled with the ethical nature of concepts perceived as being part of the sustainability agenda (e.g. the 'rights' of ecosystems, plants and animals), this multiplicity of contexts for policy formulation and decision-making provides part of the explanation for the number of competing definitions of sustainability.

Drivers for Sustainability

There are many factors that can be listed as primary drivers for the worldwide concern on issues surrounding sustainability. A non-exhaustive list would include not only factors associated with increasing resource constraints, world population increase and demographic change, globalization, the explosion of new technologies, climate change and global heating but also, significantly, the impact of social movements and the resulting political pressures that have emerged, particularly since the 1970s.

Increasing Resource Constraints

Increasing demand for natural resources of all kinds is now coupled with a realization that much of humans' use of those resources is wasteful, potentially leading to an exhaustion of non-renewable and even renewable resources. Each year, humans consume 1.4 times the resources produced naturally per year.

World Population Increase and Demographic Change

The world's population reached 7 billion in 2011 and is still rising. It is also becoming increasingly urbanized, driving the demand for more resource use and increasing emissions. Demographic changes have important implications for migration, housing, infrastructure and food supply. The world will need to double food production in the next 40 years to feed its population.

Globalization

Globalization has brought positives and negatives. Greater interconnectedness allows co-ordination of human activity on a scale unknown before and faster social change. Expanded access to information and the wider reach of the media has brought to the attention of a world audience man-made disasters such as the effects of acid rain in the 1970s, the Three Mile Island nuclear meltdown in 1979, the release of toxic gases at Bhopal in 1984, the nuclear meltdown at Chernobyl in 1986–87, the Exxon *Valdez* oil spill in Alaska in 1989, the Deepwater Horizon oil spill in the Gulf of Mexico in 2010 and the Fukushima nuclear meltdown in 2011. But it has also brought greater world awareness of issues concerning drought, famine, species extinction, habitat depletion, desertification and water resource depletion. Organizations connected with such issues can now be more closely scrutinized and by a wider audience than ever before, and there are more demands for community dialogue and participatory disaster management.

New Technologies

While the rapid increase in new technologies following the end of the Second World War brought benefits to humankind generally, there were attendant unintended consequences. Unforeseen effects of the use of DDT (dichlorodiphenyltrichloroethane) were brought to world attention following the publication, in 1962, of Rachel Carson's *Silent Spring*. The unanticipated problems that attended the use of asbestos sheeting as a cheap building material still give rise to problems with regard to safe disposal of what is now regarded as a highly dangerous material. The use of hydrofluorocarbons as refrigerants (and in aerosols) was identified as interfering with the earth's sensitive ozone layer, and the use of such compounds was eventually effectively banned following the signing of the Montreal Protocol in 1987. Thus, many of the new technologies that had been perceived as improving our quality of life (e.g. control of disease and insect pests, cheap housing, improved hygiene and food storage) came under suspicion as creating more problems than they solved. Conversely, new technologies such as generation of energy from renewable resources and computer and Internet technology not only provide significant human welfare benefits but also offer the promise of new industries and new avenues for employment.

Climate Change and Global Heating

The Intergovernmental Panel on Climate Change was established in 1988 to advise on the risks of climate change. Its first report was published in 1990. The Intergovernmental Panel on Climate Change does not carry out original research or monitor climate or related phenomena. Its main activity is to publish reports on topics relevant to scientific evidence with regard to climate change. The potential effects of climate change are now increasingly well documented. They include the melting of ice caps and permafrost, rising sea levels, increasing ocean acidity, deforestation—particularly of rainforest—large-scale species decline and extinction, more extreme-weather events (e.g. droughts, floods and hurricanes) and terrestrial desertification. There is now a widespread appreciation of the likelihood of a global average temperature rise of at least 2 °C this century, and possibly 4–6 °C, unless there is a radical shift in our relationship to the environment. Even with radical emission reduction, there is high risk of abrupt and irreversible climatic shifts taking place, possibly in the next 5–10 years, certainly in this century.

Social Movements for Sustainability

The environmentalist movement—environmental and conservation groups established at local, national

and international levels—is often identified as a key driver of change towards sustainability. Certainly, the work of venerable institutions such as the Sierra Club in the USA and the Commons Preservation Society in the UK and, operating worldwide, the activities of Greenpeace, the World Wide Fund for Nature, Friends of the Earth and the Rainforest Alliance have played an important part in highlighting the need for sustainability. However, these groups are not the only players in the field.

While there are competing claims for the origins of what has become known as the environmental justice movement, it appears that, starting in the 1960s, groups that have been associated with such a movement developed independently of one another in diverse parts of the world, yet sharing common concerns and even common discourse. This movement differs from the environmentalist movement in that it focuses firmly on issues of discrimination, racism and equity with regard to the unequal distribution of the burden of environmental degradation and on the need for appropriate community dialogue and engagement.

Since the 1960s, environmental action and interest groups have proliferated. One aspect of these groups is that they often draw membership from sectors of the public otherwise unengaged in politics. Yet the nature of their activities can often attract political attention. While some groups utilize local action or the Internet to pursue their various causes, the rise of green political parties in a number of countries, sometimes as serious competitors for political power, can lead to other mainstream parties adopting environmental policies to attract the 'green vote'. The existence of and publicity given to environmental groups and their campaigns have undoubtedly brought about changes in social expectations that have driven moves by governments to enact environmental and social legislation, and the number of multilateral international treaties and agreements

entered since the 1980s in particular is testimony to the scale of influence of such changed expectations.

It is not only governments that have reacted to these changing world views. In the world of finance and accounting, the Global Reporting Initiative aims at establishing a sustainable global economy by providing sustainable reporting guidance, the Equator Principles offer a credit risk management framework for managing environmental and social risk in project finance transactions and a range of sustainability indexes, such as the Dow Jones Sustainability Index, maintain indexes to benchmark the performance of investments in sustainable companies and funds. Business organizations, too, have become increasingly aware of the need to maintain a 'social licence to operate' and preserve reputational capital. In some fields of business, some firms and organizations have found it to their advantage to become leaders in the field of sustainable practice, pursuing what they perceive to be the 'business case for sustainability' while creating an image or reputation for their organization that has the potential to establish a market advantage for their products or services.

Organizational Change and Sustainability

Within organizations, participatory change programmes that draw on Action Learning and action research principles are frequently utilized to embed sustainability and share meaning across diverse value systems and functional areas of the organization which may have very different understandings of sustainability.

The problem of classifying organizational or corporate sustainability and appropriate change and leadership mechanisms is often addressed through a phasic approach to organizational development, such as in the use of the phase model presented in Table 1, applied to both human and ecological sustainability.

<i>Phase</i>	<i>Key Principle</i>	<i>Typical Actions</i>
1	Rejection	Employees and the environment are exploited and seen as 'free goods'.
2	Non-responsiveness	Financial factors dominate decision-making. Broader human resource and environmental strategies are ignored.
3	Compliance	Compliance with legislation and formal codes of conduct is the priority.
4	Efficiency	The focus is on systematic attempts to harness environmental efficiencies.
5	Strategic proactivity	The emphasis is on product stewardship based on a life cycle approach, strategic repositioning, product development and market redefinition to take advantage of the increasing community emphasis on sustainability.
6	Ideal phase of the sustaining organization	Priorities are renewing and replenishing social, human and natural capital

Table 1 *Phases of Organizational Sustainability*

SOURCE: Dunphy, Griffiths, & Benn (2007).

From the above discussion we can see that implementing sustainability in organizations means dealing with a multilayered and ambiguous concept, involving multiple stakeholders and value systems, with the potential to be highly politicized. Research has shown that moving between such phases is supported by employee engagement in sustainability planning and management as well as by engagement with external stakeholders. The complexity of the problem is such that a single individual, institution or business or government organization cannot enable a more sustainable future for the planet. To achieve this, we need to depend upon partnership and collaboration across sectors, among communities and between individuals from all walks of life.

For many critics, the problem lies with our obsession with growth and consumerism. New business models based on the principles of natural capitalism, such as biomimicry, adaptive manufacturing and re-manufacturing, are taking the value chain in a more sustainable direction.

Implementing Sustainability

As discussed, the material consequences of not adhering to sustainability principles are increasingly obvious through speeding climate change, increasing air and water pollution and soil and ocean degradation. Yet it is equally apparent that we face challenges in incorporating the means to address them into our pre-existing institutions and organizational systems and structures. Education for Sustainability (EfS) has been shown to be one of the more effective approaches in consciousness raising and empowering individuals to generate action around sustainability. EfS has been endorsed by the UN in the current Decade for Education for Sustainable Development, and its discourse has been embraced widely by governments and other intergovernmental bodies. While it has an educative basis, EfS is really an approach to learning and change, and its key principles can be employed within wider organizations and communities as well as in educational institutions. Action research can be an important component of EfS, and an understanding of action research is often listed alongside key skills associated with EfS, such as critical, creative and systems thinking, communication, conflict management and problem-solving.

Action Research and Sustainability

As spelt out in the Rio Declaration and *Agenda 21*, participation is an essential component of sustainability. Action research is therefore highly relevant to sustainability because certain approaches to action research can be a means of participative change, engaging individuals and communities in a reflective practice that allows them to enact sustainability in their personal

and professional lives. Action research is particularly important as a means of enabling change for sustainability because participants are encouraged to actively and systematically engage with a sustainability issue of relevance to their personal or workplace lives.

SUSTAINABLE DEVELOPMENT

See Sustainability

SYMBOLIC INTERACTIONISM

Symbolic interactionism is an empirical theory which centralizes the importance of activity. It holds that people act towards things based on the meaning those things have for them, that meanings emerge from social interaction and that meanings are modified by individual interpretation and on-going social exchange. These premises create a methodologically cohesive frame which informs a distinct process of empirical inquiry. Founded on the philosophical theorizing of George Herbert Mead and the sociological work of Hebert Blumer, symbolic interactionism centralizes meaning, interpretation and social interaction for the emergence, construction and maintenance of language, understanding and behaviour. In this entry, the philosophical foundations and methodological root images of symbolic interactionism will be described and related to action research.

Meaning, Social Interaction and Interpretation

Theoretically, it is often assumed that meaning is unimportant and can be ignored, or alternatively, human

behaviour is viewed as the product of various factors. Attention is generally concentrated on behaviour per se and the factors presumed to be creating them (e.g. psychology—stimuli, perception and cognition; sociology—status, social roles and values). Meaning is thus either merged with the initiating factors or is treated as a mere transmission link which can be ignored in favour of the initiating factor. However, in symbolic interactionism, meaning is centralized, and to ignore meaning is to neglect its fundamental role in the formation of behaviour.

This stark difference becomes clear when considering the origin of meaning. Meaning is accounted for in one of two ways. The first, realist view is that meaning is assumed to be intrinsic to the thing itself and is part of its objective nature. For example, a chair is clearly a chair—all that is needed is to recognize the meaning of the thing which is there in the thing. The second account stresses the psychical attributes connected to the thing via the individual's psychological make-up, for example, the individual's history, feelings, ideas, memories and motives. An example would be tracing the meaning of *prostitution* by examining the attitude of the person who considers 'prostitution'.

Alternatively, symbolic interactionism holds that the origin of meaning emerges from the interaction between people. Meaning is understood as being constructed, maintained and recycled from social interaction; therefore, the source of meaning is intrinsically social. Thus, symbolic interactionism does not reduce meaning to a mediating event between either psychological (causal factors within the individual, e.g., personality or personal history) or sociological (causal factors in the society, e.g., poverty or social class) factors but instead emerges in the interaction between individuals with regard to the thing, that is, the collective engagement with the thing, which creates the thing per se. Symbolic interactionism views meanings as social products, creations that are formed in and through the defining activities of people as they interact.

However, the use of meaning does not equate to the social production of meaning. That would be to reduce meaning to the application of established meanings, albeit in this instance social as opposed to realist or psychological. Instead, the importance of interpretation is acknowledged. Interpretation has two steps. In the first, the actor has to indicate to himself the thing towards which he is acting; he has to point out to himself the things that have meaning. This is an internalized social process in which the actor is interacting with himself. In the second step, via communicating with himself, interpretation becomes a process of handling meanings. The actor checks, selects, suspends and transforms meanings in the light of the situation in which they are placed. Interpretation is not an automatic application of

established meanings but is instead a formative process in which meanings are used and revised as instruments of guidance and the formation of action. In symbolic interactionism, action centrally implicates the self-interaction and reflection of meanings.

Root Images

Blumer holds that symbolic interactionism is founded on a number of 'root images' or basic ideas. These are human groups or societies, social interaction, objects, the human being as actor, human action and the interconnection of lines of action.

Human Groups or Societies

Human groups consist of human beings who are engaging in action. That is, fundamentally, human groups or societies exist in action, whether individually, collectively or on behalf of some institution or group of others. It is on this basis that symbolic interactionism carries out empirical research of human group life. For example, culture becomes understood as a derivation of what people do. Thus, terms such as custom, tradition, norm, status, role and authority refer to the relationships emerging from how people act towards one another. Human society is necessarily understood as an ongoing process of fitting together the activities of its members.

Nature of Social Interaction

As noted, symbolic interactionism centralizes the importance of social interaction in the establishment of meaning. Whilst a physical reality independent of human observation is generally assumed, it is not, however, responded to directly. Instead, humans respond to the social understandings and meanings ascribed to this reality. From this, individuals and society become understood as inseparable: firstly, as both are formed through social interaction and, secondly, as one cannot be understood without reference to the other. That is, we understand ourselves and others with reference to meanings that are socially ascribed, and in becoming constructed selves, we then engage in the ongoing construction of social meaning. Put another way, social interaction is the process that *forms* human conduct, instead of being merely a means or setting for the expression or release of human conduct.

Further, the actions of others enter into the formation of our own actions. Mead identifies two levels of social interaction: (1) the 'conversation of gestures' and (2) the 'use of significant symbols'. Blumer names them 'non-symbolic interaction' and 'symbolic interaction', respectively. Non-symbolic interactions are those actions which are responded to immediately and

unreflectively; however, human interaction is typically characterized by interaction on the symbolic level, as humans seek to understand the meaning of one another's action. Any gesture has meaning not only for the person who makes it but also for the person who receives it. When the meanings of both the recipient and the sender are in alignment, they understand each other. Mead argued that there is a 'triadic nature of meaning'. That is, any gesture signifies what the person who is making the gesture plans to do, what the person to whom the gesture is directed is then to do and the joint action that is to arise by the articulation of the acts of both. If at any of these points, there is confusion, communication is ineffective, interaction is impeded and joint action is blocked. Thus, central to joint action is the capacity to take another's role, in order to understand the other's gestural meaning.

Objects

Objects have a special meaning for symbolic interactionism. The social world is understood to be composed of objects, and these objects are the products of social interaction. An object is anything which can be referred to, whether it is a physical object (e.g. chair, tree, bicycle), a social object (e.g. mother, president, friend) or an abstract object (e.g. moral principle, philosophical doctrine, idea). The nature of any object consists of the meaning that the object has for the person for whom it is an object. For example, a chair is understood as a chair not because its meaning is housed in the 'thing' itself (i.e. it has an inherent chair-ness) but because we come to recognize a chair through sharing our understandings and interpretations of certain physical objects as 'chair'. With time, we forget the process through which we understand 'chair' as a chair and simply see the chair. However, this amnesia does not remove the social process by which we become able to understand 'chair-ness' and an object as 'chair'; a chair remains an object with socially derived meaning.

One implication of this is that human beings may inhabit the same physical space yet inhabit very different environments. As Blumer points out, humans interact and recognize only those objects which they are familiar with; this means that humans can literally inhabit different 'worlds'. But more important, it is in relation to objects that action is focused. It is through a vast process of forming, sustaining and transforming the meaning of objects that social life is played out and carried on. In bringing together different 'worlds', objects are kept in play.

Human Being as Actor

Mead argued that human beings have a 'self'; that is, human beings can be objects to themselves.

Human beings are able to recognize themselves as young, as wives, as fathers, as successful or as being in debt. Human beings must be able to stand outside themselves, taking the place of others to view the self as others view it; thus like all objects, the self object emerges from a process of social interaction. Action is carried out in accordance with this assessment of the self carrying out social roles. This ability to be an object to oneself means that an individual is in continual and ongoing social communication and construction, allowing for not only changes to interpretation but also transformation and direction of behaviour. This is radically different from understanding human beings as merely the behavioural manifestation of psychological or sociological forces.

Nature of Human Action

Human action is thus understood as being more than the result of underlying causal factors; human action is instead an active process of socially meaningful objects which are understood in conversation with an interpreting self. Whilst Blumer acknowledges that human beings may do a miserable job interpreting and constructing their actions, construct they still must. To do so, they must take into account a 'flow of situations'. This flow cannot be understood as mere factors acting through the agent, as any one factor is instead only a small element which must be considered and interpreted by the agent to understand the presenting situation requiring action.

Interlinkage of Action

Human life is then understood as lines of action which fit together. Blumer refers to this as 'joint action'—the societal organization or conduct of different acts by diverse participants. Joint action can be more than the constituent parts, for example, a marriage, a birthday party or a parliamentary debate. Nor is it necessary to identify individual participants, for example, a family, a business corporation or a nation. Fundamentally, however, joint action is collective interlinking action and is continually undergoing a process of formation. Even when the behavioural pattern is well established and routine, each activity cycle must be created anew and is open to transformation in the construction and interpretation of meaning. Joint action is also historically framed within a temporal context, that which went before informing that which is done now. To ignore the informing background of any new joint action is to effectively argue for spontaneous generation. This view of joint action challenges the notion that organizations are regularized operating systems. Instead, organizations are viewed as a diverse array of participants occupying different points in a

network engaging in their actions using a given set of meanings.

Relevance to Action Research

Symbolic interactionism can be related to action research in a profound way. Once we theoretically acknowledge that the social exchange and interpretation of meanings create a social world which is both simultaneously stable and fluid, the possibility for change in social understanding and action emerges. To put it simply, symbolic interactionism can be used to theoretically account for the possibility of change in the 'real world'.

Symbolic interactionism is founded on the notion that actors act towards objects in accordance with the objects' perceived meanings. This means that at any point our meanings and the meanings of others are open to transformation. As we reflect on our object of interest and come into contact with others' reflections on the object, our meaning of that object can change. In and of itself this would be unimportant, but it must be remembered that symbolic interactionism is predominantly a theory of activity, activity which occurs in interconnections of actors coming into contact with one another. As the social fluidity of meanings becomes apparent, activity becomes open to the possibility of change. Thus, not only does symbolic interactionism provide a theoretical account for the dynamic of change, but it also suggests meaning as an empirical lens for the study of activity change.

thinking and complexity theory. Its focus is not so much on the social, economic and organizational systems themselves as on a *systemic* understanding of how change happens and how norms become established. This distinguishes it from other forms of large-system action research that engage across organizational systems and networks, as articulated in the work of David Coghlan and Bjorn Gustavsen. There is an emerging dialogue between systems theorists and action researchers. Gerald Midgley and Ray Ison have argued for the importance of action research to systems intervention, and Bob Flood changed the name of the long-established journal *Systems Practice* to *Systemic Practice and Action Research*. Methodologies of systemic action research have been extensively developed by Yoland Wadsworth and the author. The author was strongly influenced by the thinking of Susan Weil, who established the SOLAR action research centre in the UK.

The Intellectual Underpinnings of Systemic Action Research

One of the most important foundation stones for systemic action research was laid by Kurt Lewin in the 1940s. He not only articulated the importance of action research itself but also developed the notion of a field of relations. He argued that phenomena do not exist in isolation but are interconnected through multiple relationships. His notion of a force field was a precursor to the relational understanding of power articulated by Michel Foucault, which sees power not exclusively in the relationship of the dominant with the exploited but rather as a system of constantly shifting interrelationships which create dynamic patterns of inclusion and exclusion, dominance and submission and insistence and resistance. These relationships form a 'system'. Another key conceptual underpinning has been the work of Checkland, who developed the idea of 'soft systems'. Moving radically away from the idea of systems as depictions of objective reality, he highlighted the different and overlapping systems of relationships that are perceived by actors. An understanding of multiple subjective versions of reality allows us to learn about how 'reality' might be constructed and what the systemic patterns that emerge from this tell us about how change might happen.

What follows from this is that changes in one part of the system create changes across the system. The patterns they create can crystallize into 'social norms' and other 'system dynamics'. These become powerful forces which militate against further change. Change may happen but is frequently not sustainable as power is exerted through these norms to force divergent behaviour and activity back towards the status quo.

SYSTEMIC ACTION RESEARCH

Systemic action research is an approach to action research which is built on the foundations of systems

This thinking is strongly supported by complexity theory, which shows how underlying ‘attractors’ draw people towards equilibrium points which can be sustainably changed only when strong enough alternative attractors are created.

Change is considered typically to be iterative and emergent. One thing leads to another, and each of these changes, in turn, has an impact on a myriad of other relationships within the system. This leads to emergent outcomes where there is no directly apparent relationship between the components and what emerges as the whole. This means that it can be as effective to create changes in parts of the system that do not initially seem to be the centre of concern as to focus on where the ‘problem’ appears to lie. Because of the relational nature of change, we need to be constantly alert to the fact that even changes which appear to be desirable in relation to a particular intervention may have unexpected or unwanted consequences elsewhere in the system. Similarly, positive outcomes can come from unanticipated sources.

Contrary to early systems theory, complexity theory highlights the importance of not seeing change as a linear process. The tendency to think of change in terms similar to ‘Intervention A will lead to Outcome B’ is not only a characteristic of traditional research; it is to some extent implicit in the classic action research cycle. Systemic approaches to action research enable non-simple causality to become comprehensible by seeing change as also created by multiple actions of multiple actors and as resulting from combinations of predictable and unpredictable effects. The implication of this is a shift in emphasis in both the focus of action research and the design of action research processes.

The Focus of Systemic Action Research Processes

Systemic action research has a strong focus on changing the system dynamics and building new attractors to support sustainable change. This requires an understanding of the underlying dynamics of change, and the latent attractors which lie beneath the surface until they can find expression and reach critical mass.

Many action research approaches emphasize consensus-building or collective problem-solving processes. Systemic practitioners focusing on complex problems will often be working in situations characterized by deep conflicts of interest, where there is no consensus or even joint purposes to be had or found. So the emphasis of systemic action research is often more on changing the equilibrium of a system. This does not require the acquiescence of all parties; it is rather what happens when multiple small (and sometimes larger) changes have an impact on the balance of

power within a system. So when action researchers are exploring a map which describes the system, they may be looking for opportunities, entry points, and leverage points for changing the system and not necessarily, in the first place, taking actions which they perceive will be direct answers to the issues or questions that they are seeking solutions to.

Key Characteristics of Systemic Action Research Processes

While systemic action research is built on a long tradition of action research and shares many of its characteristics, there are some aspects of its methodology which differ, amongst which are the following.

Building Pictures of the System

In order to engage with complex systems, it is necessary to observe them and then to understand them. Different techniques have been used to build pictures of the system. These often take the form of system maps. Burns has developed a multistage mapping process where action research facilitators firstly engage multiple stakeholders in inquiry, secondly produce complex issue maps where the knowledge of all the action researchers is consolidated and relationships debated and drawn and thirdly draw out of parts of the big maps to depict specific patterns and or dynamics which shed light on the wider dynamics of the issue that is being explored. These maps are then opened to scrutiny, firstly by those who generated them and secondly by the other stakeholders.

Multiple Starting Points for Inquiry

In systemic action research approaches, it is important to engage multiple stakeholders in inquiry. Different approaches to this have been adopted, with different implications. Wadsworth and co-researchers’ seminal study of acute psychiatric hospital practice in Victoria, Australia, started with a group of service-using consumers who initiated multiple dialogues with professional staff and managers. They started in one hospital ward (unit), next extended their inquiry throughout the hospital, then moved on to the area mental health system and eventually approached state and federal policymakers. The action research process tick-tacked between all participants, feeding back the results of around 35 smaller studies. At all times, the group driving the research was the mental health services user group (in effective collaboration with the other stakeholder groups). Burns’ approach was different. He has argued that in order to fully understand the system it is necessary to start at multiple points within the system. So, for example, an inquiry into female genital mutilation might separately

engage the young girls who had the practice carried out upon them, the mothers, the tribal elders, the non-governmental organizations that were rescuing the girls and the hospitals that were carrying out the practice in order to keep it clean and safe. In this scenario, a core group does not own the inquiry in the same way as it might in a Co-Operative Inquiry process.

Multiple and Parallel Inquiry Strands

This is important for many reasons: (a) to see the whole system, it needs to be seen from multiple perspectives; (b) seeing issues from multiple perspectives opens up possibilities for action which can lie in the juxtaposition of perspectives and which otherwise would not be visible and (c) complex problems are often characterized by power relationships and competing interests, which means that people cannot always inquire together in one space. As the inquiries develop, and the field of relationships is changed by the actions which have been generated from one or more of the inquiries, possibilities may emerge for different strands of inquiry to be brought together.

Fluid Inquiry Groups Which Follow the Issues

Most group-based forms of action research take the form of a co-inquiry by a relatively stable group of people, who can build trust amongst each other, and a shared inquiry history. A systemic action research process follows the issues and continuously draws in new people as they are needed, as the inquiry evolves, adding complexity for co-inquirers to continue to share a coherent narrative.

Burns sees the systemic action research approach as raising some complex dilemmas around the trade-offs between participation and a deep understanding of power and system dynamics, seeing both as critical to effective emancipator action but not always sitting easily together. In a Participatory Action Research approach, there is greater direct ownership of the process, but there may be a limited set of lenses through which to understand the power dynamics. In a systemic action research approach, more control over the process may lie with facilitators who are engaging across the system, but a much greater understanding of the dynamics of power may be achieved. This can be problematic for systemic action research facilitators, who hold the same values as Participatory Action Research practitioners and believe that the process needs to be deeply owned by the participants. In one attempt to combine systemic and participatory approaches, Ghana Community Radio Network developed an approach where the process was held and guided by community-based radio stations that developed a range of methods,

including the use of phone-ins and dramas, to deepen the participatory engagement with the inquiries. At the same time, they were able to open up inquiries with multiple stakeholders to build up pictures of the power relationships and system dynamics.

How and Where has Systemic Action Research been Applied?

Systemic action research has been applied in a variety of contexts. Wadsworth facilitated eight long-term, large-scale systemic change projects using action research in health, education and community services contexts as well as the acute psychiatry U & I project with Merinda Epstein in Australia. In the past decade, the author (with a range of different colleagues) has also developed systemic action research with a range of partners: The British Red Cross carried out a whole-organization systemic inquiry into ‘vulnerability’, SNV (The Netherlands Development Organisation) used a systemic action research approach to underpin a series of change programmes in Kenya and some other parts of East Africa, VSO (Voluntary Service Overseas) commissioned a six country systemic action research study exploring the impacts of volunteering on poverty, the UK-based National Centre for Public Engagement in Higher Education facilitated a systemic action research programme which engaged over 40 universities in an inquiry on embedding public engagement in higher education and, as mentioned above, the Ghana Community Radio Network have used systemic action research to underpin their work on climate change and have since developed systemic inquiry approaches to underpin their whole approach to broadcasting.

SYSTEMS PSYCHODYNAMICS

The notion of systems psychodynamics refers to social, psychological and political forces that underpin human behaviour in social systems of all kinds. Almost by definition, the people involved in such dynamics either lack awareness of the degree to which these forces influence them or interpret what they are aware of in a way that serves their self-interests. Action research has proven a pivotal methodology necessary for understanding and changing the dynamics in a social system—be it a family, group, organization or community, or a bigger and more complex situation.

Through using action research, scholarly practitioners can observe, explain and interpret the social, psychological and political forces that are helping the social system in (or hindering it from) being effective during normal operation or in making the changes needed for survival and growth. Bringing such dynamics to awareness for explicit discussion and debate can contribute to working through difficulties and recognizing strengths. This entry summarizes this type of action research, using six dimensions linked historically to the Tavistock Institute of Human Relations (TIHR), the research and development organization in London, UK, often given credit for its original formation and early application to workplaces.

Framing the Change Situation

Action research from a perspective of systems psychodynamics tends to start with concerns about organizational culture and persisting difficulties in working well together. Commissioners of such action research may speak to unhelpful attitudes or poor motivation within a section of the social system or, indeed, across two or more parts of a larger organization. Often, leaders link strategic challenges currently under way or anticipated with an out-of-date historical or societal element in employee behaviour. Education, social services, health care, religious organizations and government systems

illustrate sectors in which this framing of change originated.

Role of Consultant and Stakeholder in a Typical Change Approach

Scholarly practitioners working predominately from a systems psychodynamic perspective use developmental interventions that create meetings and workshops for people to work through difficult thoughts and feelings about relevant aspects of a challenging change. The role of the consultant tends to emphasize observation, analysis and interpretation. Of particular concern are types of social defences people enact as they avoid anxieties. Those people with a stake in the change process usually take responsibility for making conclusions, planning actions and otherwise identifying outcomes from the process of working through. This type of action research often works well alongside other, more familiar types of change management.

Nature of Intervention and Character of Participation

A central orientation of intervention from a systems psychodynamic perspective can be understood to be process consultation. Many types of intervention can be used: individual coaching or counselling, third party consultation, small groups, inter-groups, medium or large groups. In order to work with the emerging data, scholarly practitioners need to be in a participant observation role. This allows them to discover and then share verbally tentative hypotheses with the people in the room. Alternately, working notes can be written and circulated for a wider population to study. Generally, the consultant retains a specialist role while encouraging employees to increase their competency in sense making and in taking up roles to improve their situation.

Dynamics of Social Stratification

Studying authority relations and the impact of social stratification on the total situation are two phenomena of particular concern for systems psychodynamics. The underlying theory is that people position themselves in relation to authority figures much as they experienced in their childhood and early years. Psychological and political dynamics can be stirred, observed and explored in the relationships between bosses and workers, higher status and lower status roles and those with more and with less influence. By bringing differences into focus, developmental work can help people reclaim their productivity and authority in their roles.

Intra-Organizational and Inter-Organizational Issues

Action research from a systems psychodynamic perspective typically focuses on intra-organizational change and development. A major purpose of this perspective is to address thoughts and feelings of being unable to make a difference within individual and collective roles as well as in individual and collective working relationships. The social system in its environment will be worked with in terms of similarities and differences in how people experience it from various roles, subunits and levels. A shared sense of what they are facing in relation to the world outside the organization will be seen as essential. Instead of splitting (some know and care, while others do not), all people need to take action from every position within the organization and across boundaries to interact effectively with clients, customers, regulators and so forth.

Nature of Work With Feelings and Fantasies as a Contribution to Learning for Change

Working with feelings and fantasies as a way of enhancing learning for organizational change can be understood to be a basic methodology of systems psychodynamic action research. Scholarly practitioners often specialize in depth psychology through formative education or advanced training. Subjectivity is understood as intricately interconnected with peoples' aspirations for objectivity and rationality. Thus, feelings and fantasies are considered normal, coexisting or dominating at different points to help or hinder, respectively, and have no discernible impact one way or another on productive work. Working subjectively, however, aims to discover non-logical, non-obvious interconnections. By bringing these to awareness, blocks can be released, and escalations calmed down. Generally, discovering emotions about tangible issues and challenges in the social system brings increased freedom and a better atmosphere for making differences to the total situation.

SYSTEMS THINKING

Systems thinking is an approach to understanding and improving complex issues and situations. It attempts to deal with these as wholes rather than through the reductionism of conventional science. Reductionism understands complex issues by examining smaller and smaller parts. Systems thinking sees the whole as different from the sum of its parts, because of the interactions between the parts. The issue for systems thinkers then becomes one of defining a relevant whole. The way this question is answered leads to a variety of approaches to systems thinking. This entry presents an overview of these ideas and outlines the history, development and current state of systems thinking and its links to action research.

A System and Systems Thinking

Unlike in traditional science, the whole, or the *system* of interest as it is called, is never separated from its environment. Traditional science has as some of its basic tenets reductionism, randomization, replication and independent observation: It strives to be value-free. While such science has been very successful, there are many issues of concern that it is not possible to tackle through this approach due to their complexity, uncertainty and changing nature. It is these issues with which systems thinking engages. Systems thinking is thus a complement to traditional science, not a way of thinking that is trying to replace it. Rather than isolating a part in a controlled environment for the purpose of designing an experiment, systems thinking always considers the system and its actual environment as an integrated whole and looks at how best to intervene to improve a situation or issue.

Systems thinking is linked to action research because of its interest in improving situations and issues rather than just observing them. When systems thinking is used to assist in an intervention into real-world situations, it is called systems practice. Many of the developments of systems thinking have occurred either through the explicit use of action research or through the implicit use of its principles. Other aspects that systems thinking has in common with action research are the participation of those involved to a greater or lesser degree and learning from the experience both of improving the issue of concern and of the practices used to achieve that improvement. Ideally, those involved also decide what constitutes an improvement.

In addition to its commitment to holism, systems thinking sees relevant systems as themselves being made up of systems—known as subsystems. It is the interaction between these subsystems that leads to emergent properties that make the whole different from the sum of its parts. These emergent properties cannot be predicted from knowledge about the subsystems. In the same way, the system's environment is a wider system of which the bounded selected system is a subsystem. Thus, there is a never-ending hierarchy, and systems thinkers need to use their judgement to decide the appropriate level of the hierarchy at which to select the systems of interest to improve. The bounded system selected is seen as preserving an important set of relationships between its subsystems and the wider system (environment).

The qualities of systems thinking described in the above paragraph are referred to as identity, boundary and emergence. Others include communication and control, negative feedback that leads to stability, positive feedback that leads to change and purpose—which when defined from outside the system's boundary is referred to as *purposive* and when defined within the system's boundary is referred to as *purposeful*. Finally, systems are seen as open, if they interact with their environment, or closed, if they do not.

History and Development of Systems Thinking

Ideas within systems thinking can be traced back to Plato and Aristotle and can be seen in the conceptualization and practice of many historical figures since, including Leonardo da Vinci, Johann Wolfgang von Goethe and other holistic thinkers. However, systems thinking as it is known today emerged during the 1940s from within the field of biology, where it was recognized that an organism was more than just a collection of parts and that an understanding of the parts of an organism did not tell you all you needed to know to understand that organism and how it might respond in any given environment. Rather, knowledge was also needed about how the parts interact and communicate, how control was achieved and what the organism's purpose was. Systems thinking quickly led from natural science to social, cognitive and management sciences, and on to philosophy.

Early approaches to systems thinking defined the whole—the system of interest—quite objectively, and these approaches had little in common with action research. This early work drew together people from widely different fields and led to the emergence of hard systems thinking, as it is now known, which includes operations research, systems analysis and systems dynamics.

The pioneers came together under the title of general systems researchers and included Ludwig von Bertalanffy (biology), John von Neumann (mathematics), Kenneth Boulding (economics), Anatol Rapoport (mathematics), C. West Churchman (philosophy), Russell Ackhoff (organization theory) and Geoffrey Vickers (law), followed by Jay Forrester, Donella Meadows, Peter Senge, Humberto Maturana and Francisco Varela. Concurrent, and often in association, with this group emerged the field of cybernetics—or the science of control in steering towards a goal. The key figures here were Norbert Wiener, Ross Ashby, Gregory Bateson, Margaret Mead, Stafford Beer and Heinz von Forrester. The initial aim of both general systems thinking and cybernetics was to find universal, mainly mathematical, models that could be applied in a trans-disciplinary way; however, this original goal was soon dropped. This is often referred to as the first wave of systems thinking and had little explicitly in common with action research, although aspects of these bodies of work continue to influence the work of many action researchers (see, e.g., Bateson).

Subsequent waves of systems thinking share the underlying principles of action research, most notably its interest in intervention as much as observation, where such intervention strives to meet some human need or desire. When used to aid such intervention, systems thinking becomes systems practice. Observations of intervention cannot be independent or value-free—indeed, many would argue the same for traditional science, but this is explicitly accepted in systems thinking. It was Churchman who first raised this concern and who noted that the selecting of a boundary for a relevant system was a value-laden activity. Much subsequent work in systems thinking builds on his concern for the positioning of the boundary. Alongside this, reflecting critically on an intervention is now a key aspect of systems thinking. The other common principle it shares with action research is that of participation, although different strands of systems thinking deal with participation in different ways.

As many of the early systems thinkers encountered intractable issues which were irresolvable through the use of mathematical models, many moved into second wave systems thinking. A key figure here was Peter Checkland, who explicitly used action research during the 1970s to develop his approach to what came to be called soft systems thinking. Others in the USA also used Churchman's ideas about systems to develop other soft systems practices. In cybernetics, the move was towards the *cybernetics of cybernetics* and the beginnings of a consideration for learning in both a theoretical and a practical sense: Soft systems thinking was seen as a learning approach to change, yet little consideration was given explicitly to the learning process as such.

The third wave of systems thinking developed from the 1990s onward and drew insights from social theory to deal with issues of power and to attempt to respond to the challenges of postmodernism. The work of Michael Jackson, Robert Flood, Gerald Midgley, Werner Ulrich, John Mingers and Norma Romm was influential here, developing ideas that led to what emerged as critical systems thinking and its associated systems practices of total systems intervention, critical systems practice and systemic intervention. All these have features in common that include methodological pluralism, boundary judgement, intervention and critical reflection, and they have much in common with action research, as demonstrated by the title of one of the main systems journals, the *Journal of Systems Practice and Action Research*.

There was a fourth wave of systems thinking; learning systems had its origins in the exploration by Bateson of the logical types of learning, second order cybernetics and soft systems thinking as a learning approach, as well as in the double-loop learning of Chris Argyris and Donald Schön. However, for all of them, there was little consideration of systemic learning as such.

Systemic learning was the focus of what became known as the Hawkesbury approach, led by Richard Bawden. Drawing on the experiential learning theories and practice of David Kolb and on insights from developmental psychologists, particularly Marcia Salner, who linked this field to systems thinking, the Hawkesbury group drew out theories from their praxis of systemic development—their learning approach to change.

This approach recognized that modern education and society are grounded in the world view of reductionist science, and so the first step to becoming a systems thinker is to *appreciate*—a term proposed by Geoffrey Vickers—different world views. It is not that one world view is the best but that different people hold different world views based on differences of ontology (e.g. objectivism and relativism), epistemology (e.g. holism and reductionism), axiologies (notably ethics, e.g. utilitarianism, deontology and virtues) and aesthetics. Appreciating complex situations and intractable issues through a dialogue about a variety of world view perspectives can lead to the emergence of potential improvements. Different methodologies and methods associated with different world views assist this process. These *epistemes*, or world views, are often tacit, and it is through explicit, critical reflection on these as part of a social learning process that improvements may be proposed.

There are three levels of learning in this systemic learning process: learning about the situation or issue, learning about the learning methods used (meta-learning or double-loop learning) and a third level of reflecting on the *episteme* or world view reflected by the first two levels and critiquing its strengths and weaknesses. This

third level leads to the potential adoption of other world views through the use of alternate methodologies. Collaborating on this process with a group of stakeholders potentially enables a social learning process.

Also recognized is the important role of inspirational learning in helping draw insights for participants in the creation of meaning—the end, purpose or significance of something. Thus, systemic learning combines learning from the outer world of experience, the inner rational world of conceptualization and the insights of the inner human spirit. As a learning system, this will all occur in an environment of emotions, power and dispositions that need to be considered. These theories have been extended into the wider field of social learning and Etienne Wenger's communities of practice by Chris Blackmore and Ray Ison in the UK and Europe.

Conclusion

Systems thinking has emerged since the 1940s and continues to develop. Many of the original methodologies have changed as theoretical developments unfolded, such as operations research transforming into soft operations research. Key principles have emerged, however, that have much in common with action research. These include (a) ensuring the incorporation of multiple perspectives that adopt different world views; (b) using a range of methodologies to put this principle into practice; (c) understanding and using the processes of systemic and social learning in a critically reflective way, particularly through the facilitation of dialogue amongst experts and stakeholders; (d) being context specific yet ensuring that critical reflection allows for wider implications and principles to be drawn out and made publicly available and (e) applying systems thinking through systems practices that lead to improvement in issues of mutual concern in ways that are systemic, responsible, sustainable and defensible.

T

TACIT KNOWLEDGE

Tacit knowledge is a term concerned with the nature of human knowing and was first introduced by the Hungarian scientist and philosopher Michael Polanyi (1891–1976). His radical idea is summed up in the bold claim that ‘all knowledge is either tacit or rooted in tacit knowledge’. The relevance to action research is that Polanyi is offering a basis for theorizing human action that involves implicit knowledge, skill, know-how and so on. The challenge that Polanyi poses is that even though tacit knowing is inherent to practically all human experience and action, it seemingly remains inexpressible and difficult to make explicit. Until now, his notion of the tacit nature of all human knowing has been largely ignored by modern epistemology, which has been largely concerned with ‘knowing that’ rather than ‘knowing how’, and his work has also been marginalized by recent writers in the philosophy of science. However, as a vast precognitive resource, tacit knowledge is emerging as an important field of research. One area where tacit knowledge has been recognized as having a particularly crucial role to play is in the organizational and management sciences. Such ideas could even anticipate the prospect of a major paradigm shift for the human sciences. This entry reviews Polanyi’s concept of tacit knowledge and provides examples of how this kind of embodied knowledge operates in our everyday lives. The role of tacit knowledge in organizations and its application to action research are then discussed, and finally, a model which recognizes objective, discursive and participatory forms of knowing and articulates a strategy for enabling tacit knowledge to be made explicit is presented.

Personal Knowledge

Polanyi expanded his Gifford Lectures of 1951–2 into his magnum opus, *Personal Knowledge*, published in 1958. In this text, he stresses the vital and inescapable

role that the personal plays in all human knowing, skill, action and experience. Polanyi proposes that ‘all knowing is personal knowing’, involving ‘participation through indwelling’. In this way, he offers a radical challenge to the simplistic view of normal science; he argues that at the root of claims to objective scientific knowledge, there is always reliance upon personal knowledge. He characterizes these ideas, central to his philosophy, as a post-critical philosophy.

This idea of personal knowing has previously been outlined by other philosophers in their various ways as a kind of knowledge by personal acquaintance, by familiarity with an object, event or situation. This dates back to the ancient Greeks and their idea of a practical knowledge, a knowing by doing. In more recent times, key thinkers such as Hermann von Helmholtz, William James, John Dewey, Bertrand Russell and Gilbert Ryle have all in some way discussed a notion of knowledge by acquaintance. However, Polanyi has, more than anyone else, tried to theorize and explain what knowledge by acquaintance might actually entail. His argument for the participatory, tacit nature of all human knowing is still groundbreaking.

Furthermore, Polanyi’s philosophy bears resemblance to what lies at the heart of Martin Heidegger’s notion of ‘being-in-the-world’. What Polanyi calls participation through indwelling seems to correspond to Heidegger’s notion of ‘readiness-to-hand’. Heidegger describes this as a dealing with things that are closest to what it is to be human, by which he means a kind of ‘concern’ involved in manipulating and using things that we find in our world. He sees this ‘concern’ as having its own kind of knowledge, and presumably precognitive. Indeed, considering the tacit as having its own kind of knowledge lies at the heart of Polanyi’s philosophy.

Polanyi’s Tacit Dimension

Although what we know by personal acquaintance may be available to some extent in our personal awareness, Polanyi proposes that we are simply not aware

of a great deal of what we know at all. It is this that he calls tacit knowing. By defining the tacit in this way, he is pointing out the knowledge that is implicit to a task (e.g. as know-how, skill), to a situation (e.g. when travelling, interviewing, cooking), to a perspective (e.g. reflecting a point of view, a belief) and so on.

The tacit is precognitive, similar to John Searle's notion of 'background', and is historically grounded in direct participatory experience, in other words, by personally taking part in some previous activity. It manifests through circumspection, experienced in forms of know-how, skill, expertise, coping, knack, adaptability, improvisation, affordance, absorption and so on. It is knowing that, when called upon by a particular situation, it is made effortlessly available.

The key to understanding Polanyi's tacit dimension is in the distinction he makes between focal and subsidiary awareness. When engaged in any action, awareness is necessarily divided between the goals of the task at hand and the component 'sub-skills' necessary to complete the task. For example, as I type this text into my laptop, my focal awareness is upon what I am trying to express, and I only have a subsidiary awareness of the spelling of words and the rules of grammar. I do not consciously think about the position of the keys on the keyboard or the finger and hand movements I make, let alone the eye movements being made between the screen, my notes, the keyboard and the kitten playing on the floor. Yet if a problem arises, any of these aspects can be brought into focal awareness, although at the expense of a disruption in my writing flow. Polanyi's point is that the knowledge which is operating at this subsidiary level is tacit and that if we are asked how we are able to engage with such a task, then there would always be more that we 'know', more than we can actually tell. For Polanyi, knowing is *action*, tacit knowledge is *embodied knowing*.

Tacit knowledge is not something that is necessarily learned explicitly, rehearsed or committed to memory. It is participatory knowing, in other words, knowledge from participatory experience, by indwelling, simply by being somewhere, doing something, engaged in extended practice. Later, within the context of a specific situated action, tacit knowledge is made available, efficiently and immediately, for the task at hand. Two brief examples will make this clear.

Maps are schematic; map-reading is a complex skill. Consider the map of a city you are visiting. Buildings may be indicated but not represented by their height and style of architecture, distances may be very difficult to estimate, walking routes may be obscured and detours may be required on arrival. Skilled judgements are needed to locate your current position, involving improvised comparisons between the physical environment where you find yourself and the schematic representation of the map. You intuitively work out a route

to follow. All of this creates as well as draws upon a wide range of complex tacit knowledge which you are hardly aware of. Alternatively, because of little previous participatory experience, in other words, a lack of tacit knowledge, the map might prove useless; you risk being lost or you fall back on other tacit knowing that circumvents using the map. Furthermore, it should be obvious that your tacit knowledge of the city after just one brief visit bears little resemblance to the limited knowledge gleaned from the map. The feel of the place, its ambience, the construction work in hand, detours, helpful signs, the people, facilities, a bookshop, that café, the day's weather and so on are all coded for subsidiary use. You end up with a personal mental map, with its own emphasis, meanings and interpretations. Perhaps later, helping someone visiting the same city, you draw a map for them. But no matter how good your map, it cannot capture all the knowledge you have of the place you visited. There is always more than you can tell.

For a second example, consider the problem of following instructions for some self-assembly furniture recently delivered. You open the pack, find the instructions and study them carefully. What you do next will heavily depend upon just how methodical is the strategy that is incorporated into your tacit knowing, for example, how you will count and arrange the components or find the tools necessary for the task (including knowing where to find them). With luck, the furniture is built in no time. But either from problems that emerge or by simply using reflection-in-action, it is quickly realized that the instructions are merely a set of ordered steps for the assembly process and do not describe how this is to be done. The instructions do not specify which tools to use for which operation, let alone how to use the tools properly and safely. Nor do they tell you how to position and glue the parts together, let alone prepare the glue for use and clean up the mess it undoubtedly makes. No instructions can make allowances for the particular workspace available or the specific help you need if you have limited strength and capacities. Normally, most issues are sorted out by tacit knowing operating at a subsidiary level of awareness. This knowing is not mechanical or 'automatic' but is responsive, timely, dynamic, idiosyncratic and invariably creative, drawing upon resources from participatory experience. Such knowing is difficult to make explicit. It is easier to show someone else how to do something, and let them try it for themselves, than to tell them explicitly how. Letting someone learn for themselves is precisely what the tacit dimension advocates from its theory of human action.

Tacit Knowledge in Organizations

One field where the concept of tacit knowledge has made a significant impact is knowledge management,

but this is not an area without its controversies. Haridimos Tsoukas has pointed out how the concept of tacit knowing has been misused, and how Polanyi is being misunderstood. He explains that Polanyi has sometimes been wrongly interpreted as simply describing a kind of ‘hidden knowledge’ that merely requires the right procedures to be made explicit. In addition, it is a field that needs to be approached with some caution concerning notions such as ‘knowledge economy’ and ‘knowledge capital’ and an overconfidence in the idea of ‘capturing’ tacit knowledge. However, this is a relatively new and pioneering field of inquiry, and inevitably, organizations will have their obvious focus on the commercial value of knowledge, fuelling naive discussions about how tacit knowledge can be communicated and made explicit.

New Methodologies for Action Research

Recognition of the tacit nature of human action requires rethinking research methodologies. As an immeasurable precognitive resource, tacit knowledge is not straightforward to elicit or to research; it cannot simply be ‘captured’ and made explicit. But ways are beginning to emerge. For example, human narrative is emerging as an important resource for sharing what is tacitly known. When confronted with something that is unexpected or out of the ordinary, we can effortlessly seize upon a narrative which places the events into some context. In turn, such intuitive narrative thinking can easily be communicated to someone else in the form of a story. In this way, narrative becomes a vital means by which the tacit can become explicit.

Reflection-in-Action

Another approach, which has been illustrated in the examples discussed above, involves the close interrogation of experience. This is an empirical phenomenological approach employing reflection-in-action, which is repeatable, reproducible and confirmable. In this respect, Dvora Yanow and Haridimos Tsoukas have reframed the work of Donald Schön in a Heideggerian way, describing a phenomenological mode of reflection that takes place in the midst of action. In turn, they relate this to the tacit nature of the background knowledge that accompanies all human practice. This promises to become a key tool for action research.

Moustakas’ Heuristic Inquiry

Polanyi’s philosophy has also been incorporated by Clark Moustakas into an approach that he calls heuristic inquiry, which explicitly emphasizes the participatory role of the (co-)researchers in the research process. Polanyi’s influence is clearly seen in Moustakas’ core

conceptual framework, which includes the following: personally identifying with the focus of the inquiry, researcher self-dialogue, intuition, indwelling, focusing and discovery of tacit knowledge.

Developing a Model for Human Knowing

Currently, what is needed is a model of human knowing that includes a view of human action as participatory, embodied and enactive (in the sense that actions express the underlying tacit resources). One solution is presented in Figure 1, which treats human knowing as an overlapping, threefold practice. The three practices—objective, discursive and participatory—are complementary and not in opposition. Human action takes place in three realities: physical, shared and personal. Such a model offers the prospect of a paradigm shift in the human sciences, which might properly incorporate the tacit dimension.

TAVISTOCK INSTITUTE

An extensive portfolio of project work undertaken by the Tavistock Institute of Human Relations (London, UK) exemplifies action research as an integral methodology for understanding and contributing to change and development in a broad range of social systems. The Tavistock Institute of Human Relations was established as a registered charity in 1947 from a previous base as the Social Department of the Tavistock Clinic. Its explicit purpose was to study and encourage effective human relations under both normal and unusual circumstances. Members of the founding association cared deeply about how to use social science to find a way to help people cope with stresses and to thrive in a society emerging from the two World Wars.

Initially supported by a grant from the Rockefeller Foundation, Tavistock Institute staff became early pioneers in using action research as a way to rebuild or otherwise create renewed social infrastructure: with individuals and their families, in workplaces and communities and through governmental policies at local, regional, national and European levels. This entry summarizes some well-known action research projects from the Tavistock Institute's early decades, selected particularly because their dissemination sparked innovations around the world. This entry goes further to indicate action research during subsequent decades that tends to be lesser known, although of equal integrity given a different funding environment. These examples from the overall portfolio of work have the added advantage of illustrating how social scientists at the Tavistock Institute continue to approach action research.

The Socio-Psychological Perspective

The Tavistock Institute's socio-psychological approach was so labelled because an important shared enterprise at the time was to understand how people—usually without awareness—placed their psychological issues into the social situation in which they found themselves.

Through action research, it was possible to study what was being enacted in the social situation, to hypothesize how that enactment might be related to unresolved psychological issues being experienced by the people and to craft social experiments and other system changes intended to clarify and resolve psychological issues. This angle was the mirror opposite of the approach of the Tavistock Institute's sister organization. Post-World War II, the Tavistock Clinic entered the new National Health Service as a psychoanalytically orientated mental health outpatient unit: Its strong innovation at the time was to discover, describe and work with ways in which the social situation contributed to psychological issues. Indeed, several founding members of the Tavistock Institute association maintained some involvement with the clinic as well. However, the interest in psychological issues as being enacted and reinforced in the total social situation resonated with the institute's increasingly diverse associates, comprising sociologists, political scientists, social anthropologists, operations researchers and social psychologists.

Combined with a nascent action research methodology that gathered data from many people within any one social situation, integrated teams of social scientists began to notice multiple and simultaneous influences on human behaviour. They used and taught each other how to use a wide range of concepts from depth psychology to social anthropology, to political science. Such an approach felt both grounded in the reality of the people whom they were trying to help, as well as pointing out unusual ways to change organizational aspects of the social situation in order to address the psychological. The institute found that a simultaneous socio-psychological approach enabled them to understand and contribute to development and change in a wide variety of situations. Here are three examples of influential action research projects with a predominantly socio-psychological perspective.

Transitional Communities and Social Reconnection

This project assisted British prisoners of war with resettlement as civilians once they were repatriated. They often felt disorientated and experienced difficulties with reintegrating with their families, jobs and wider communities. A period of collective living with others, combined with a developmental programme of activities with specialists, was worked out, with steady improvement through cycles of action research.

Working Through Industrial Conflict

Based in a service department of Glacier Metal Company, this project helped management and workers collaborate on difficulties in changing their payment system. Through many discussions using existing

committees, interdependences became apparent between morale, methods of payment and inter-group conflict. Action research helped them make progress by also taking seriously cultural issues, administrative practices and technological changes.

Social Systems as a Defence Against Anxiety

This project started as a diagnosis of problems in training student nurses within a general hospital. Unusually high levels of stress and anxiety were leading to withdrawal from training by student nurses and changes in jobs by seniors. Careful action research eventually drew attention to the way work practices and organization contributed to stress. While senior nurses intended to cope with strong emotions related to the main task of dealing with terminally ill patients, aspects of their processes and procedures made things worse.

The Socio-Technical Perspective

The Tavistock Institute's socio-technical approach was so labelled because the circumstances for several industrial action research projects concentrated on social problems that seemed interrelated to the introduction of new technologies. After the publication of a book based on the Glacier Metal Company, requests for assistance increased, and the institute selected fellows from industrial clients to be trained in fieldwork. Now, social scientists (external to an organizational client) were paired with industrial fellows (internal to that organizational client or a similar sector): Together, they actively combined field-based data collection methods from social anthropology with group-based psychoanalytically informed practices to test the usefulness of tentative findings. Cycles of research, action and reflection—in collaboration with small groups within different parts and levels of the organization—led to evolving understandings about what was happening, as well as leading to actions intended to improve aspects of the social situation relevant to technological change.

A breakthrough came when one industrial fellow pointed to an innovation in work practice and organization created by front-line employees. Through action research, it was possible to understand that the workers did not maintain a tight distinction between what they wanted and needed at work—job satisfaction and social structure—and the satisfactory performance of their duties. When the new technology introduced by the company disrupted what they needed, they changed how they worked in order to continue to get their needs met. Tavistock Institute's social scientists considered that they were discovering a new field of inquiry,

which they termed *socio-technical systems* design, and a new approach to working that countered scientific management and semi-autonomous working groups. Subsequent action research led to an extensive body of theoretical and practical literature aiming to optimize both the socio-psychological needs of employees and the technical needs embedded in the work. Here are three examples of influential research predominately from a socio-technical perspective.

Longwall Coal Mining Cycle

When the British Coal Board introduced mechanized coal-getting equipment, one manual role persisted that was treated as if it was part of a cross-shift team. This led to several difficulties that decreased productivity with the new technology: private arrangements to help each other out, personal secrecy about better places at the coal face, cross-shift scapegoating and absenteeism as defiance. Using action research, it was possible to understand the socio-psychological needs requiring attention through changes in work practices and organization.

An Indian Automated Weaving Shed

When the calico mills in Ahmedabad first introduced an experimental building (called a shed) with automatic looms, they did so using methods of time and motion studies common to scientific management as related to the cyclical process of operating a single loom. But the task of running an automatic weaving shed constituted a continuous process of multiple looms weaving and all roles and tasks being completed simultaneously. Using action research, a new social organization in relation to two main types of automated looms—based on groups with all the various roles working in relation to an identified set of looms—began iterations of improvement until both social needs and productivity goals were met.

Stepwise Socio-Technical Systems in a Petroleum Company

Automation of chemical processes motivated Shell UK executives to undertake action research for the purpose of addressing alienation and poor performance throughout, aiming for a more participative management style. Large-group meetings to review and revise a draft document—co-ordinated by a small, internal employee relations group, with help from the Tavistock Institute—cascaded down through executives, senior managers and local refinery managements. Subsequently, two pilot refineries undertook an innovative stepwise methodology for detailed analysis and implementation of socio-technical systems.

The Socio-Ecological Perspective

The Tavistock Institute's socio-ecological approach was so labelled because, in collaboration with people engaged in change and development within their organizations, action researchers increasingly revealed that the changing environmental contexts of organizations was a key factor in their broader social field. Successes with interdisciplinary, collaborative projects on work practices and organization resulted in a different sort of project that placed social scientists at an apparent boundary between inside the organization and outside the organization. Decision-makers within both public and private large enterprises needed to take account of anticipated futures 'out there' and their potential impact on separate organizational entities.

By this time, the Tavistock Institute's blend of theory and practice had made great strides in bridging the traditional splits between psychology and sociology. Multidisciplinary social scientists and industrial fellows had stretched open-systems thinking in order to define a task environment for organizations that included customers, supply-chain relationships and statutory regulations. At the time, to consider that the environment might be in continuous flux—as both input and output for people in social systems—required an extension of the theoretical framework. This was nothing short of accepting that 'out there' needed to be conceptualized as a practical field of study—directly and mutually interrelated in the total social situation for individuals' psychological issues. Here are three examples of influential action research predominately from a socio-ecological perspective.

Causal Texture of Organizational Environments

In an effort to make sense of several large-scale action research projects, the Tavistock Institute's social scientists accepted the notion of 'boundary' as a functional arena for human relations, instead of as a structure that separated inside from outside. Thus, they experimented with four links between a social system and its environment: (1) parts within the same system, (2) output to the environment, (3) input to the system and (4) the environment. Their resulting hypothesis was that the system and its environment were mutually determinative, with different qualities of environment providing limits and opportunities for organizational strategic choice. These qualities were labelled as placid, randomized; placid, clustered; distributed, reactive and turbulent fields.

Referent Organizations and the Development of Inter-Organizational Domains

An increase in government-funded action research projects required multi-actor collaboration within

particular public and private sectors or across regional, national and international boundaries. This work challenged the ways of thinking about an organization as a single entity, thus placing the institute's social scientists in positions of working with representatives from several organizations simultaneously without a single authorizing body. Socio-psychological methodologies helped with crafting inter-group and institutional discussions, as did the large-group methods emerging from socio-technical systems work. But the ability to work with the complexity and uncertainty characteristic of these inter-organizational domains raised new action research challenges: competing economic and political interests, regulatory decision-making processes and contested societal values.

Overcoming Adversarial Relations Across an Industry

Paradoxically, several projects came about once government and industrial leaders agreed on social systems changes for the benefit of both society and business interests. In one instance, their proposed solution of strategic partnerships often faltered. The Tavistock Institute undertook action research over several years within the UK construction industry to assist those people who were authorized to decrease adversarial relations between the multiple firms involved in new buildings. Court battles over legal contracts, spiralling costs, overruns on delivery times—all plagued the typical 30-plus specialist firms that struggled with the interconnected nature of designing, planning and managing a build. Action research focused on cultural changes as related to workflows and necessary collaborative deliberations.

Experiential, Participative and Cross-Boundary Applications

Social scientists continue to interweave three types of action throughout the Tavistock Institute's interdisciplinary research. Experiential learning, participative decision-making and cross-boundary interactions initially emerged from careful consideration of solving problems with applied social science theory. At the time, these actions were unusual, running counter to models of objective science and autocratic leadership of change. But it was precisely through action research that the necessity of these actions emerged for both analyzing and enabling changes within the particular social situation.

Experiential Learning in Groups

Action research at the Tavistock Institute uses an approach that optimizes developing theory and

improving practice. Its group relations programme continues to surprise staff and participants as they discover how the psychological can be discerned with the social and how the social can be linked with the ecological. Known as the ‘Leicester conference’ after the English university that serves as venue, working conferences combine experiential learning, participative decision-making and cross-boundary interactions. Group-based study configurations include individual role consultation, authority relations in small groups, formation and dynamics between groups, dynamics between subunits and stratification in institutional contexts.

Strategic Choice and Interconnected Decision Areas

By blending operations research for urban planning with interactive working in decision-making groups, the institute’s social scientists demonstrated how complex planning tasks could be used for adapting strategic choices. This multi-actor, cross-boundary work proved a significant application of all three institute perspectives. Pioneering city planning departments accepted the notion that to conceptualize such large, complicated projects as a single organization grossly underestimates the evolving volume of multiple, simultaneous initiatives needing continuous co-ordination and mutual adjustment.

Participative Evaluation Research

Through its own projects as well as its international journal named *Evaluation*, the Tavistock Institute has led the dissemination of innovative approaches to evaluating social policy, especially those that actively involve multiple shareholders in interpreting and using their own data. Instead of emphasizing judgements, participative evaluation focuses on processes of ongoing learning in order to facilitate change. For an evaluation to have real impact, policymakers and funders are challenged to move beyond a summative, measurement orientation and to support more formative, developmental orientations. For example, an extensive action research project across 20 UK sites, addressing better delivery of information to citizens, used several methods: case studies, quantitative surveys, qualitative interviews and Action Learning.

Developing Capability in Social Engagement of Social Sciences

The notion of ‘the social engagement of social science’ reflects the fact that the Tavistock Institute of Human Relations thrives on an underlying, value-based commitment. Its articles of incorporation explicitly relate multidisciplinary social science to the needs and concerns of human beings, from individuals, groups and

organizations through to communities, industries, governments and society overall. As an independent, not-for-profit organization, the institute has had to make its own way financially in the world while honouring its founding values. This has often meant joining others in learning how to engage socially with social science—action research has been pivotal in this endeavour.

Human Relations

From its earliest days after World War II, the Tavistock Institute’s journal aimed to integrate multidisciplinary social science for the purposes of contributing to both the theory and the practice of effective human relations under both normal and unusual circumstances. The underlying three perspectives, discovered and developed through action research projects, were published in full—sometimes over several issues. Many decades later, and despite numerous competing journals, *Human Relations* remains one of the premier publications in fields having to do with organizational change, social policy and human behaviour in a wide variety of situations. The relationship between theory and practice, especially as it relates to contemporary relevance for managers and leaders, continues to drive editorial policy.

Education for Organizational Change and Related Consultancy

Learning to take up a role as manager, leader, consultant or some other agent of systems change requires individuals to be aware of a wide range of social science as well as to have developed substantial self-understanding and capabilities in working within groups and across boundaries. The Tavistock Institute has experimented with a range of ways to provide education and development with just such a layered learning agenda. Scientific staff, guest scientists, industrial fellows and action research interns have undertaken psychoanalysis, attended group relations working conferences and served on teams for multiple field projects. As professional development and postgraduate programmes increased in number, the institute made its mark with various offerings, for example, the advanced organizational consultation programme, practitioners’ certificate in change and consulting and coaching for leadership and change.

Action Research ‘House Style’

Institute staff found that a single orientation for applying social science was too limiting in addressing the depth and breadth of the social issues they were challenged to consider. Thus, their interest in cross-disciplinary and multidisciplinary working emerged.

Early on, some common principles from field theory guided their collaborations. Field theory took as its fundamental premise that people and their surroundings and conditions depend closely on each other. This meant that the institute's scientists found it necessary to take a dynamic approach, discovering multiple forces at work in any situation. As the basis of action, they concentrated on elements of the current situation that motivated or otherwise influenced people and their situation. By coming up with constructive ways of presenting and discussing such complexity, those involved could be helped to shape their own change. This house style persists in the Tavistock Institute of today.

TAYLORISM

In 1911, the American engineer and management consultant Fredrick Winslow Taylor published a tiny book called *The Principles of Scientific Management*. The book referred to the experiences Taylor had while conducting experiments on improving the efficiency of work processes in a steel company through so-called *time studies*. In retrospect, the book stands out as probably one of the most significant management books ever written and is the bible of the management ideology called 'Taylorism'. By introducing a radical division of labour between managers and workers, this book is constitutive of our modern conception of the organization of working life. It has been a central point of reference for discussions and practices of management and organizing, both as a source of inspiration and, not least, as a target of critique. Although highly criticized from the beginning, the ideology still seems to diffuse in ever new practices and technical disguises

(Business Process Re-Engineering, Lean Production, etc.). Thus, most approaches to management and organizing relate to this work in one way or another, explicitly or implicitly. This is also true of the branch of action research that addresses the management and organizing of working life, the industrial democracy tradition of action research. This entry expands on the concept and the impact of Taylorism in modern working life and outlines how the industrial democracy branch of action research has been developed as a reaction to Taylorism.

Basic Principles of Taylorism

The principles of scientific management (hereafter SM) according to Taylor (1998) can be summed up as follows:

- A radical division of work between manager and worker, where the manager will have the full responsibility for developing and designing the procedures and the organization of the work processes, leaving the workers the task of enacting or implementing the work

The managers' tasks will thus be to do the following:

- Assess scientifically the best way to perform the tasks and outline them in a specific scheme of actions that can be distributed to a series of actors performing simple actions instead of complex ones
- Select the best persons to perform the tasks according to scientific methods
- Guide and train the workers to perform the tasks efficiently
- Monitor the performance of the workers to ensure that the procedures are followed and the expected result achieved
- Treat the workers as individuals—create systems of incentives and learning addressing the individual workers rather than the collectivity of workers

Taylor's principles of management and organizing gained a lot of influence within industrial work from the early and mid twentieth century, associated with standardized mass production of, for instance, cars (so-called Fordism, even though many sources claim that Ford did not know about Taylor when he designed his first mass production factory). It has also contributed to the enlargement of bureaucracies, as systems of standardized and impersonalized routine processing and implementation of decisions.

What has been termed by Ritzer as *McDonaldization* of service work is basically Tayloristic in its

management and organization. The concept of 'lean operations' that is currently mushrooming through both private and public sectors internationally is another example. By using expert observation and analyses as a basis for redesigning all kinds of tasks, from surgical operations at hospitals and care work within nursing homes to processing of insurance cases, these 'lean' strategies of change are typically Tayloristic. Specific management technologies like 'balanced scorecard', measuring specific performances and so on are often claimed to be practised in a Tayloristic way

The purpose of the principles of SM was, according to Taylor, an entirely humanistic one. Their aim was to contribute to the prosperity of modern American society and, at the same time, to the prosperity of the individual worker by rationalizing work to increase productivity and output both for the owners of firms as well as for the workers. However, this humanism has been widely disputed. The principles of SM can be characterized as typically modernistic, building on a positivist conception of knowledge, believing in the possibility of developing objective and universal knowledge about the one best way of working. It builds on a notion of a fundamental difference between experts, with their formalized knowledge, and lay people, who lack significant knowledge. It builds on an essentialist view of the difference between 'working men' and 'educated men'. Further, it builds on a simplified conception of man as *Homo economicus*, primarily motivated and engaged by securing his physiological and material needs. On this basis, Taylorism has 'fuelled' a vast range of alternative approaches to management and organizing that take a critical stance towards Taylorism for carrying great human costs, creating a democratic deficit in the society, preventing employees from developing competence and creative abilities and not even ensuring productivity in simple repetitive work operations. Examples are the human relations school of labour relations, organization development and motivation theory.

The Industrial Democracy Branch of Action Research

The industrial democracy branch of action research is also conceived as a reaction to Taylorism, in line with these general critical views. With conceptions of socio-technical design of work processes, psychological job demands and semi-autonomous groups, the industrial democracy tradition contributed an important and influential share of alternatives to Taylorism. However, what has turned out to make the action research approaches particularly viable in the long term compared with other alternative approaches to Taylorism were not the alternative models and ideologies of

management and organizing as such. Rather, what today seems to be the most important contribution of action research is the challenge to Taylorism related to its concept of knowledge, and thus its failure in the development and implementation of knowledge for the improvement of working life.

In this sense, action research shares with SM the premise that improvement of the organization and performance of work processes should be based on research. However, SM's concepts of research-based knowledge differ fundamentally from those of action research. Where SM rests on positivism and the general belief in expert knowledge, action research builds on the premise that knowledge is situated in character and needs to be extracted from the experiences of the actors involved in the (work) situations where the knowledge is to be used. Thus, emphasizing the significance of *the process* of improving the organization and the performance of tasks, the industrial democracy branch of action research has developed from experimenting with specific alternative models of organizing to the organizing of continuously co-operative learning processes, for instance, in the form of Dialogue Conferences, Development Coalitions or organizational learning. This is done through democratic dialogue: Here, employees, managers and researchers are engaged in doing action research in their own organization (and situation) as part of its daily operation, bringing their various experience and knowledge to the table. This approach to improvement in working life acknowledges the impossibility of finding universal solutions to optimal organization and performance. Instead, it emphasizes the significance of the ability of organizations to continuously learn and develop their operational conditions and situations. In this way, action research also avoids being co-opted and turned into an even more efficient vehicle for Taylorism, as has been the fate of many models of organizing initially launched as alternatives to Taylorism.

TEACHING ACTION RESEARCHERS

Teaching action research is not teaching students *about* action research but facilitating their learning of a complex research practice that integrates conceptual knowledge with lived experience. Unlike most traditional educational experiences, this involves co-generation of knowledge on the part of the learner through being engaged with other students, all of whom are learning how to be action researchers through active inquiry. Specific pedagogical designs vary based on the institutional setting in which action research is taught, and for what purpose. However, most seek in one way or another to reflect the action research process itself in how it is being taught. In other words, teaching action research is a practice of involving the learner in the cognitive processing of conceptual information while engaged in praxis.

Common to all action research initiatives are the goals of empowering the researchers to solve pertinent problems that are confronting them while producing new practical knowledge. The intended outcomes

of action research vary across a spectrum, from the empowerment or emancipation of community members through taking action on problems within their social setting, to contributing scientific knowledge relevant to a broader academic or social discourse. Achieving these outcomes requires initiating and taking collaborative actions, fostering critical reflection on the process and the outcomes of having taken those actions, along with rigorous data analysis, synthesis and writing reports about the knowledge generated.

Conducting action research requires a researcher to have a complex mix of competencies in social or group dynamics (to organize the process in a collaborative, democratic way), personal and collective reflective learning practices (to enhance reflexive awareness of how the actors are intervening in the setting and are thus embedded in the study itself) and research methods (for contributing robust conclusions to the relevant scientific/social discourse). Conducting action research involves applying this mix of capabilities in real social environments where action produces unexpected as well as intended consequences. Effectively navigating dynamic social settings entails blending tacit intuitive knowing drawn from lived experience and formal conceptual knowledge into practical application. Practising action research requires being able to manifest this blending in the moment, engaging in what Donald Schön describes as reflection-in-action and reflection-on-action with others. Teaching action researchers how to manifest this complex skill set involves creating pedagogical designs that mirror the practice itself. In short, learning how to do action research and, by extension, teaching it involve engaging in a pedagogy involving praxis—reflection and taking action in the world to change it while obtaining new insight and understanding from doing so.

In addition to learning the above skills, students need competencies in data gathering and analysis. Data-gathering competencies include interviews, field observation methods, working with archival data, focus groups, constructing and conducting surveys, as well as inferential statistics. Coding data, thematic analysis and triangulation are critical analysis capabilities. Learning to effectively perform these research skills also requires understanding how to select the right mix of methods for the project at hand, including sequencing them appropriately. There is no pre-given formula for making these decisions. As Morten Levin has stated, the research question and project objectives determine the methods to be applied.

Approaches to Teaching Action Researchers

A rich and diverse literature exists on the process, roles, methods and skills of action researchers. However,

less attention has been given specifically to how these aspects of action research need to be taught. The practice of teaching action research within the context of higher education is complicated by the dominant institutional culture of higher education that focuses on lecture and discussion of the existing theoretical literature in the field of study. The dominant paradigm in universities is teaching research from the perspective of doing research *on* subjects rather than *with* participants who are partners in the research.

Recently, however, experienced action researchers who have grappled with the challenge of teaching action researchers in a range of higher education institutions across the globe have written about their pedagogical approaches and the challenges they commonly face in implementing them.

Challenges in Teaching Action Research

Action researchers teach distinct groups of learners in terms of academic level (undergraduate, master and doctoral students, including Ph.D., D.B.A. and Ed.D., among others) and in terms of varied professional motivations for engaging in action research (e.g. emancipatory and/or community revitalization broadly conceptualized, addressing problems related to organizational performance, contributing to the social/behavioural sciences). Regardless of the focus, a number of teaching challenges must be recognized in preparing to offer courses, or a programme, preparing action researchers. Some of these are embedded in the complexity of the action research process itself, others in the epistemological underpinnings of action research, which significantly contrast with those dominant in higher education institutions.

Paule McNicoll notes six challenges encountered when teaching action research, in contrast to teaching more conventional forms of research, whether quantitative or qualitative, experimental or traditional field research: (1) initial struggles of students to adopt a new frame of reference regarding the nature of the research, (2) issues in grading student performance, (3) recognition of ethical concerns and gaining approval from institutional ethical review boards, (4) time limitations placed on academic courses by academic programme structures, (5) balancing tension between research and action and (6) the centrality of the group process. While this is not an exhaustive list of challenges, it captures a wide range of dilemmas described by action researchers teaching action research.

Many students come to action research with the epistemological role model of maintaining an objective stance towards their environment embedded in their frame of reference. This is particularly true of those students who have taken traditional research courses

that emphasize maintaining the subject/object split, with reactivity on the part of either the researcher or the research subjects seen as potential validity threats. This is also true of many professionals whose training is framed in terms of acting *on* the system and not as collaborators whose actions are a part of the system and reflected in the performance of the system. When first encountering the epistemological assumptions of action research, some students are sceptical of the practice, at least from a research perspective. Paule McNicoll suggests that one way of beginning to address this challenge is having students actively engaged in developing their own research questions addressing problems for which they want to seek practical answers. Through the process of planning and piloting their projects, a new understanding begins to emerge, leading to a fundamental shift in their perspective. Experience, not logical argument alone, is what creates new frames of reference.

Another challenge involves the grading of student performance. Grading practices in higher education are very test focused. The emphasis is on acquiring content knowledge and then answering questions. Alternatively, papers are assigned along with structured guidelines. The scored test or paper is assigned a grade. In contrast, assessing learning in an action research context involves observing the growth that takes place as the student develops his or her project while applying newly acquired conceptual knowledge and engaging in critical reflection throughout the process.

There is wide agreement among action researchers that in teaching action research, it is important for the teacher to model the relationship that needs to be fostered between the student action researcher and the other participants. Accordingly, more of a mentoring or coaching role is adopted, asking questions, making recommendations and documenting the growth of the student. Papers written by the student may be marked with asterisks throughout, noting questions from the professor regarding the content of the paper. The student submits responses to the questions. Papers are drafts to be reworked, not final assessments. William Foote Whyte argued that writing and rewriting is part of the research process. The researcher is having a conversation with his or her experience and data.

Similarly, provocative questions raised by the professor during discussions about decisions made in the field by the student stimulate reflective practice, as well as reinforcing certain principles of action research.

Another challenge is getting projects approved by university ethics committees, whose assessment criteria conform to traditional experimental and field research designs that are largely pre-structured. Given the emerging nature of an action research project, with the design co-developed with participants and evolving

over the course of the project, traditional criteria for approval cannot be met. Prior to engaging the participants, specific research questions cannot be defined. Nor can all the actions that will be taken be identified prior to initiating the research project.

Strategies for addressing this challenge will vary across institutional contexts. In every case, however, these strategies will involve educating key members of the committee about the intentions and values of action research, along with developing allies on the committee. In part, this includes not minimizing the importance of the committee's work. Davydd Greenwood has recommended developing an ongoing dialogue with the chair and other members of the ethics committee, helping them better understand action research and building a relationship of trust. Other strategies include having a subcommittee that handles these projects with a designated contact who is in communication with the researcher throughout the project.

The duration of action research projects varies greatly and is somewhat unpredictable. Consideration needs to be given to what aspects of the teaching process can be completed within a set time frame that corresponds to the semester structure of the institution and what aspects need to accommodate unpredictability. Solutions vary from having particular modules placed between extended periods of time that are administered similarly as internships or practice classes to year-long sequences of modules that the faculty member administers flexibly.

Taken together, the tension that exists between research and action, and the challenge of group dynamics involve the conducting of meaningful emergent research in the midst of a change process. While efforts can be made in the class setting to simulate the dilemmas that often emerge over the course of an action research project, such simulations cannot capture the ambiguities and power dynamics that emerge when working within a community in which participants hold varied agendas and interests. The student must learn to balance and integrate the capturing of data while in the midst of maintaining a focus on helping forge effective action. This often involves the researcher struggling with the aforementioned challenge of absorbing a new definition or framing of research even while organizing the project. In the process, he or she has to incorporate the participants into the research process. It is not unusual for participants to be more interested in solving the problem that they seek to resolve. Initially, they may have little tolerance for the need for gathering research data and documenting their experience. These are just two of the conundrums that foster initial issues of group dynamics. Navigating these kinds of challenges is again learned through experience, including reflecting with the teacher on missteps made by the

student in the field, with the teacher in a mentoring or coaching role.

Interestingly, the above challenges mirror many of the conundrums frequently described by experienced action researchers in reporting on their own practice. Teaching action research requires confronting and modelling ways of addressing the challenges students need to learn to navigate and resolve in their practice.

Pedagogical Designs for Teaching Action Research

The challenges discussed above contextualize the pedagogical approaches for teaching action research. Within this context, a pedagogical design must be crafted for developing the complex mix of skills and competencies described in the introduction to this entry. Pedagogical designs for teaching action research are consistent with adult education theory. Levin and Ann Martin have argued that adult education theory emphasizes the need for learners to be self-directed as they learn to apply skills through experience and engage in critical reflection. They emphasize that developing engaged researchers requires creating learning spaces that involve the students as self-directed learners. Their argument is consistent with experiential learning theories, such as David Kolb's learning cycle of having an experience, reflecting on that experience, making meaning through conceptualizing the experience and then, consistent with the work of Kurt Lewin, experimenting by taking new action. Levin and Martin note that a pedagogy for teaching action research builds on the Freirian belief that emphasizes that teaching directly through projects that address problems of personal concern to the students is foundational for fostering self-directed learners.

The emphasis on adult education is also strongly emphasized by Chris Kenyon and Stewart Hase, who have coined the term *heutagogy* in place of using the term *pedagogy* or Malcolm Knowles' term *andragogy*. Their point in using the term *heutagogy* is to emphasize the importance of self-determined learning as students are placed in non-linear situations that can be highly disorienting for those trained in traditional research and problem-solving methods. As the learners get increasingly embedded in the complex practice situation, their frame of reference begins to shift towards engaged research.

While there are significant variations in programme designs depending on the student population being trained, a review of the literature on teaching practices reveals that in one way or another many pedagogical designs utilize learning groups or sets, with the students actively engaged with each other while they develop, implement and write up their projects. These designs

incorporate the seminal work of what Reg Revans described as Action Learning sets, where people learn together while working on real-world problems. Action Learning is a process through which learners integrate what Revans called 'P', or programmed learning—acquiring conceptual knowledge—and 'Q', or questioning insight through working on a real-life quandary. Again, the theory is that working on real problems of importance to the learner generates self-direction. This is consistent with the position of action researchers involved with teaching the practice, such as Levin and Johan Ravn, that teaching action research involves creating spaces for learning about Action Learning while acting.

Shankar Sankaran, Bob Dick, Ron Passfield and Pam Swepson have made explicit the connection between action research and Action Learning, providing several examples of using action research and Action Learning as part of a pedagogical approach. Shankar Sankaran and Tay Boon Hou describe how teaching action research has been explicitly combined with Action Learning in order to enable doctoral students who are managers in companies to more easily obtain permission to use action research in their organizations for their thesis. Framing their thesis projects as a process of Action Learning emphasizes the benefits to be derived by the organization and provides a workable framework for the pedagogy. The integrated learning process consists of three interconnected cycles, each of which evolves through the learning cycle of plan, act, evaluate and conclude.

In this programme, developing and conducting the thesis as action research is framed as a cycle evolving through the action research process: (a) *planning* around the research project to address the problem; (b) *taking action* by initiating the thesis project in the student's organization; (c) *evaluating* through observation, reflection and theorizing and (d) *concluding* by creating the first draft of the thesis. This first cycle intersects with the second cycle, when the planned action research project is implemented as Action Learning, with cycles of planning, acting, observing and reflecting with participants. The final cycle is the writing of the thesis—plan the final draft, act by writing the thesis, conclude and submit. These three cycles reflect what in learning theory is described as a stable core of plan, act, reflect and conclude, with flexible and interacting cycles taking place within the stable core.

As Action Learning is often characterized as one variation of action research, it provides a workable framework for designing an effective pedagogy. The faculty member is functioning both as the expert providing just-in-time programmed knowledge and as an Action Learning coach facilitating the experiential

learning of the student. Dick has designed a web-based one-semester course for Action Learning students called Action Research and Evaluation on Line, which is offered through the Action Research Action Learning Association. Initially developed to provide a convenient source of 'P' learning on topics related to action research and evaluation in support of thesis students, it can also be taken for free for non-credit. Students use the discussion list for dialogue and raising questions while engaged in completing assignments. The continuing enhancement of web-based technologies can facilitate the communication around set members who are geographically dispersed while implementing their projects in local sites.

Conclusion

Teaching action research can be a challenging (and rewarding) process. It involves teaching a complex mix of competencies using pedagogical designs in which the professor transitions from a collaborating expert to a coach and a mentor. The process has to be one of engaging self-directed learners. Such designs do not fit well with the traditional institutional structures and practices of higher education, which are based on the transmission of codified knowledge from instructor to student.

Consequently, designing and conducting a programme for training action researchers is itself a process of Action Learning on the part of the faculty. Levin has described variations of a Ph.D. programme at the Norwegian University of Science and Technology. Each cohort had a different mix of students, with the design reflecting lessons learned from the prior one, which is itself a process of engaged praxis.

TÉCHNĒ

The term *téchnē* is Greek. Linguistically, it is at the origin of everything ‘technical’ or ‘technological’ in modern languages. In modern contexts of action research and professional practice, *téchnē* is often presented with *phrónēsis* and *epistēmē* as knowledge forms introduced by Aristotle (384–322 BC). It is usually interpreted as a technological or mechanical knowledge form. With *epistēmē*, interpreted as ‘science’, *téchnē* is used to describe ways of knowing dominant in the modern period, with which action research mostly does not want to be identified. The following text presents central aspects of *téchnē* as it was coined through the philosophy of Aristotle.

Téchnē Is Art

The original meaning of *téchnē* is ‘art’. Like the Latin *ars* and the English ‘art’, it carries double meanings. *Ars* and *téchnē* indicate what a modern ‘artist’, and also what an ‘artisan’ and a ‘technician’, does. On the one hand, it indicates something creative and expressive for which there hardly exist clear rules and where skilful and mindful discretion is decisive. On the other hand, it indicates something technical, in other words something which by definition is strictly rule-based, drill-based and almost mechanical. *Téchnē* is both art and craft, which modern languages tend to separate. Every artist may need to be an artisan, and an artisan should preferably be an artist as well. But today, poetry belongs to the creative and expressive pole, while everything technical belongs to the rule-following, drill-based and mechanical pole of the old *téchnē*.

Téchnē Is a Way of Reasoning

With Aristotle, *téchnē* is a specific way of using *lógos*, in other words, a way of reasoning or using reasoned speech. In a wide sense, *téchnē* is connected to any consciously intentional and knowledge-based activity provided with a method. A *technitēs* was ‘an expert’, and *téchnē* could mean ‘articulate, skilled expertise in any field or subject’. According to Aristotle, there are several ways of using *lógos*. Finished science requires deduction. Research or unfinished science works dialectically or dialogically. Both have theoretical aims. In a different ‘department’, there was *phrónēsis*, which is deliberative (*bouleútikē*), and *téchnē*, which is mainly calculative (*logistikē* or *logismós*). Both *téchnē* and *phrónēsis* are non-theoretical in an Aristotelian sense, since they aim at and deal with what changes or is brought into existence, depending on what we ourselves do. They concern things that one can produce

and control, in other words, choose, decide on, initiate, change, develop or stop so that the variation depends on people. Still, their ways of bringing about change and using *lógos* differ.

Téchnē Immanent to Making and Using

In a narrower sense, *téchnē* is inherent to the specific kind of knowing or activity called *poiēsis* (‘making’, ‘creating’ or ‘bringing forth’) and, by analogy, to *khreōsis* (‘using’), in other words, to the ability to manipulate, move and form external objects (as materials or as tools) according to the preconceived concepts, aims and plans of a separate user, artisan or artist and where the end and aim is an ‘artefact’, a product or condition formally separate from and external to the process of producing it or arriving. Having built a house, the process stops; having reached your destination by car, you stop using it. *Poiēsis* could be tacit and without *lógos*. *Téchnē* is the specific form of reasoning and articulation connected to *poiēsis*. Thus, *téchnē* and *poiēsis* indicate something ‘artificial’, in other words, something made by art, something non-natural, something that does not happen naturally or by itself. But Aristotle also emphasizes that true art does not go against nature but supports and complements it. *Téchnē* may restore nature where nature has gone astray, as in the best forms of medical practice where the artificial in a sense exceeds nature. Nature (*phúsis*) and *téchnē* differ in that natural change springs from forces, sources and principles internal to the changed object while *téchnē* imposes change upon the object from the outside.

Téchnē Versus Phrónēsis

According to Aristotle, the less events happen by chance (*túchē*), in other words, where there is a predictable order and regularity, the more *téchnē* can take over. Where there is room for chance, however, there is also room for volition and deliberation. Also, *epistēmē* and *lógos* provide a free space for deliberation and choice since the same knowledge can produce the opposite results, for example, medicine can produce both health and disease. Deliberation and discretion are needed in fields or cases where there are no precepts. Where clear rules and precepts exist, technique and *téchnē* enter. *Phrónēsis* is deliberative on behalf of ethical virtue. As deliberation, *phrónēsis* is prescriptively and normatively advisory, exhortative and admonitory, while *téchnē* and *poiēsis* intervene. As intervention, *téchnē* or technical reasoning is basically calculative. Knowledge-based calculation and intervention presuppose stable connections between applied causes and resulting effects in the objects to be manipulated and affected.

Although human beings, relations and affairs can be studied, treated, manipulated or conditioned like objects or animals, they do not strictly comply with these requirements since new insight and understanding (epistēmê and lógos) may make people realize that they are being manipulated or that they are ruled by stimuli, habits, conventions and traditions. Discovering and grasping an ingrained habit or reaction, or a pattern of conduct, could make it possible to break it (doing the opposite). Also, in human affairs, questions about what to do, requiring deliberation, and questions about what really is going on here, requiring critical interpretation and understanding of particulars (*sínesis*), keep reappearing continuously in action. There is no téchnê, nor do any precepts (*paraggelía*) exist for doing this, since accidental properties are infinite and may even be merely imagined or arbitrarily defined, and the same thing, or some such accidental aspect of a thing, may seem pleasant to some, harmful to others and merely useful or completely indifferent to still others.

Téchnê as Applied Epistēmê

Aristotle says that téchnê does *not* deal with particulars the way phrônêsis does and that téchnê does *not* deliberate (*ou bouleúetai*). This suggests that téchnê is a form of applied epistēmê. Téchnê, then, narrowly defined, is a deductive application of general epistemic knowledge of ‘high regularity’ in creating the changes planned and induced by us, where the application of a certain cause can be calculated to produce the same chain of effects regularly. This is done with the use of lógos by the technician(s) in a certain phase, in finding and applying the right stimulus as a cause and in calculating the ultimate effect as the result of a chain of predetermined causes in the objects concerned. But it is done without any use of lógos in persuading or convincing the manipulated or influenced object itself to react in certain ways or in showing and giving it reasons and justifications for choosing, acting or reacting in certain ways. Mindless material objects do not need, and are also quite unable to receive, that kind of communication. They are not invited as sharing members and colleagues into the communicative group. Hence, if téchnê in the narrow sense is applied to other people, it does not primarily relate communicatively to their minds by sharing thoughts through lógos and by providing advice and counsel. It relates interventionally to their bodies or souls, fixing bodies and conditioning their habits, emotions, desires and actions.

Speaking ‘Technically’ or Communicatively

In contrast, phrônêsis is practical reasoning (aiming for action) based on mindfulness and understanding

in the ‘objects’ to be influenced—in other words, co-subjects, co-thinkers, co-actors who understand the meaning of what is said. Phrônêsis exhorts, admonishes and appeals to humans’ independent, reasonable minds through valid arguments, reasons, justifications and observations to heed certain particulars when acting in order to attain some specific result. For téchnê in the narrow sense, however, the other is a thing. Speech, used technically, is an influencing force among other forces, where the effect on others is what counts, not the validity of the intellectual, cognitive content of something said and communicated. Understanding in the recipient has nothing, or only accidentally something, to do with the technical effect of spoken words. As part of poíêsis or khrêsis, téchnê calculates effects on human beings as well as on other objects. In human relations, this form of téchnê is the mastery of influencing, manipulating and using other human beings.

Although, after Aristotle, Stoic philosophers were in many ways formalists in their reasoning, the wider meaning of téchnê became more salient in Hellenistic times (330–31 BC) as, in their term, *téchnê peri tòn bion*—in other words, *ars Vivendi*, or ‘art of living’. The Stoic ‘art of living’ covered much of what for Aristotle was best covered by phrônêsis, in other words, human affairs. The clear distinction between téchnê and phrônêsis, emphasized by Aristotle, thus became more blurred in later philosophy.

Téchnê in Action Research

For action research, the term *téchnê*, both in a wide and in a narrow sense, raises interesting questions about the nature of the relationship between researchers and whatever is researched, between knowers and the known and between ‘change makers’ and others. Inspired by Lewin’s dictum ‘You have to change it in order to understand it’, many action researchers see their activity as interventions, taking their models from medicine or engineering. This may be seen to be a form of téchnê. Others find inspiration in the concepts of praxis and phrônêsis. Understanding and mapping how these differ, overlap or interact should provide food for thought and for important discussions within the community of action researchers.

used with respect to organizational development. Using Jürgen Habermas' theory of knowledge-constitutive interests as a springboard, they distinguished *technical* action research from *practical* action research guided by an interest in educating or enlightening practitioners and from *critical* action research guided by an interest in emancipating people and groups from irrationality, injustice and harm or suffering.

To Theodor Schatzki, these three kinds of action research differ in their 'teleoaffective structure' in that the overall structure and purpose of each, or *teleos*, involves different kinds of emotional, or *affective*, investment.

Foundational to how TAR has been defined by critical educationalists is the view that TAR reflects a technical approach to reasoning where the means to an end are seen as the focus of change or improvement rather than the ends or the broader political, historical and sociocultural contexts in which a practice is located. This critique considers that technical approaches to action research are not truly owned by or empowering for participant practitioners and are not transformative or critical. In other words, TAR is underpinned by certain values and assumptions and not by others. The concession is that it may provide a springboard for practitioner-initiated inquiry and, in some contexts, lead to more critical and participatory forms of action research.

TAR as a discernible form of action research has a longer history than the term itself. The pragmatic quality of TAR is evident in the contributions of John Dewey. Kurt Lewin's field experiments have been cited by writers such as Bjørn Gustavsen and Ian Hughes as reflecting the TAR characteristic of the researcher's role being clearly distinguished from that of participants. Others, such as Davydd Greenwood, see action research as undertaken by action research experts who work with local stakeholders. A great deal of action research has been undertaken where the inquiry has been initiated by government, management or researchers, including those undertaking postgraduate projects.

Writers such as Michel Thiollent suggest that action research and participatory research have different lineages which have converged to some extent since the 1980s. Distinguishing technical from participatory forms of action research occurred at the same time.

Action research can be considered technical for a range of reasons. In TAR, the researcher's role is clearly distinguishable from that of the practitioner, consistent with the notion of the researcher being an *outsider* as opposed to an *insider*. Outsiders according to Olav Eikeland are generally researchers, consultants, therapists, educationalists, social workers or others whose institutional base and primary practices are not embedded in the specific field of practice that is

TECHNICAL ACTION RESEARCH

Technical action research (commonly referred to as TAR) is one of many suggested types or modes of action research. The primary purpose of TAR is improving the outcomes of a practice or an intervention. The focus of the inquiry process is typically determined by parties external to those directly involved in the practice, with action research techniques used by an external researcher or facilitator to identify or improve practices which meet predetermined ends. Examples include the testing of external findings in practice, the exploration of practice or organizational methods to achieve a particular desired outcome and the improvement of existing ways of doing things. This entry discusses the history and characteristics of TAR, together with consideration of the contexts of its application.

The interest in distinguishing TAR can be located in the critique of positivist-scientific enquiry. The term was first used by the Australian writers Wilfred Carr and Stephen Kemmis in the mid-1980s in the context of wanting to distinguish a critical and emancipatory form of action research for education from what was seen as a more practical orientation of British action research

the focus of the action research. Whilst such outsiders come and go as part of particular projects and may engage in substantial collaboration, they are nonetheless highly influential in establishing the terminology, the techniques to be used and the theory produced from the action research process.

TAR broadly encompasses action research underpinned by *positivist* assumptions about how problems are best understood and responded to. TAR in this sense can be thought of as action research located in the conventional norms of social research, as opposed to the emancipatory and political location of more critical forms. Action research has been used in variously termed inquiry approaches, including applied research, Intervention Research, action experiments and Action Science, where partnerships between researchers and organizations have the goal of generating new scientific knowledge. A number of dynamics might help explain the reported increase in popularity of forms of action research which have a technical character. These include the discourse of evidence-based policy and practice, the challenges of implementation in relation to complex issues and environments and managerialism.

TAR has also been suggested as using a particular form of reasoning. The focus of this reasoning is on instrumental change or *techniques* embodied in notions of *efficiency* and *efficacy* rather than transformed social relations. An over-slavish use of the action research cycle to structure the inquiry process rather than engagement with social and collaborative richness has also been suggested as a consequence of reducing action research to a technical form.

TAR has been used in a wide variety of contexts. It has been used in institutional contexts where practitioners require a significant level of mandate and endorsement from management to undertake action research processes, as a framework for evaluation of a programme or intervention, to develop interventions which better appreciate the contexts of their application, to develop and improve social programmes and as a methodology for scientific and quasi-scientific studies in fields such as agriculture, engineering and management. As action research has been applied in various settings, there has been criticism from critical action research and Participatory Action Research theorists that the true values of action research have been subsumed to technical purposes.

A feature of the application of action research since the 1990s is the diversity of forms it can take and the contexts it is applied within. Many contexts are institutional in nature and bring with them particular social, political and material relations. According to Michel Thiollent, action research is increasingly practised in larger projects, incorporated into institutional

arrangements involving government, research bodies and organizations. Much of this use is within neo-liberal environments and has something of the character of TAR, given the broad alignment of action research with institutional goals and endorsed outcomes. In Australia, the use of action research within the Reconnect early intervention into youth homelessness programme is one such example. The broad outcomes of preventing homelessness provide a politically and organizationally endorsed parameter for action research into improving practice, though what practices and micro-questions are specifically investigated is left for each funded service and their practitioners to determine.

TAR has clear applications in contexts where representational knowledge outcomes are prioritized. There are limitations if TAR is used as a stand-alone approach to inquiry. TAR is a normative construct in that it is defined by critical action research theorists as being at best an intermediary platform en route to more desirable forms of action research. It is better understood as an archetypal category of action research which is used in contexts where the focus and the meaning of inquiry are necessarily limited at least in the short term to deepening understandings around agreed objectives and where the impetus for inquiry has its origin outside of those most central to the practice.

Approaches to defining action research can reflect a static view or one that is dynamic and developmental. A dynamic and developmental approach considers that the characteristics associated with ideal forms of action research (participatory or critical) develop over time and that the role of the action researcher is to facilitate and maximize such development. The definition of action research developed at the Australian National Action Research Symposium in 1989 reflected such a developmental approach. Other writers such as Yoland Wadsworth have discussed the way researchers often work over time to assist research subjects to become their own researchers or co-researchers, effectively transferring power as engagement, understandings, relationships and skills develop.

How action research is defined continues to evolve. Schemas for distinguishing various types of action research highlight particular characteristics seen as central from a particular vantage point. TAR is characterized by its focus on technical goals and the location of research power as external to those undertaking and affected by the practice in question. Whilst TAR may have collaborative aspects, it contains elements of research *on* or *for* people rather than research *with* them. Writers such as Susan Adler have suggested that the technical improvement and democratic enhancement goals of action research are contradictory.

A feature of the literature since the 1990s is the emergence of more nuanced understandings of how roles,

purposes, scope and context interact in various action research processes in quite complex ways. As part of this, there has been recognition that dichotomous categories inferred by terms such as *participatory*, which implies that an approach is either participatory or not, do not match the reality of utilizing action research in real-world contexts typified by complexity. As suggested by Bob Dick, Appreciative Inquiry has developed as a constructivist approach that aims at large-system change through an appreciative focus on what already works in a system rather than what is deficient. This mirrors the development of strengths- and asset-based approaches in clinical practice, community development and organizational practice.

A number of shifts in action research relevant to TAR are evident in the twenty-first century. The application of complexity theory means that dualisms such as inside/outside have less cogency given there may be many participants and stakeholders who engage with each other at various levels of horizontal and vertical integration, evident in different aspects of their activities. How top-down policy and governance measure the interface with participatory bottom-up processes becomes a critical focus for conceptualizing social change processes. How various forms of action research are defined and how the role of technically oriented processes is understood continue to be of interest.

regular jobs in an organization and want to contribute and succeed but, at the same time, are treated as outsiders because they represent ideals, agendas, values or even identities that are somehow at odds with the dominant culture. Their stance as outside insiders can be a disturbing force, shifting organizations in the direction of incremental change. Shaking things up is their *modus operandi*, with a penchant for making change from within organizations. In effect, tempered radicals are the change makers who put to meaningful use the methods of action research.

Tempered radicals favour action, the type of action that represents their values and beliefs and the difference that makes them who they are and how they contribute to their organizations. Action research and its varied methods privilege moment-to-moment inquiry in action. The courageous stance of the tempered radical to invoke and initiate such processes is essential. Action research methods interweave first, second and third person spaces. The subjective first person experience focuses on self-awareness and is important because the change leader must be authentic and wholly present to be effective. In addition, the intersubjective or second person space of interpersonal communication and interactions emerges as the tempered radical works with a team to enact a change in the system. Finally, the objective third person space which enables the change leader to see the system in its totality, to envision and create impacts and observable outcomes of action, is necessary to ensure that the vision driving the change is realized. Each of these enables tempered radicals to maintain their curiosity about the intentional actions that may lead to sustainable organizational transformation over time.

Tempered radicals are people who operate deep within big companies, well beneath the cultural radar, who are a part of the organization as professional irritants, employing many different styles and strategies. They work to slowly change the rules. Action research requires advocates who are willing to hold steady in the face of uncertainty and inquire into potential pathways for action, direction and resource recruitment. Tempered radicals who employ the strategies of action research, such as reflection, deep inquiry and dexterity, in speaking the unspeakable have two special capacities. The first is their capacity to tentatively fit the context they find themselves in while, at the same time, shaping and reshaping themselves to remain within that context and make change. The second capacity is their ability to live in the paradox of change making. Such curious, tempered agents of change have the capacity to endure a state of ambivalence while small shifts take place within an organizational system. Their capacity to remain curious rather than to prematurely seek resolutions to systemic challenges or organizational

TEMPERED RADICAL

In this era of unavoidable rapid change, economic globalization, hyper-compression and ambiguity, the role of the tempered radical is essential. Tempered radicals are self-described as organizational insiders who have

conundrums makes them excellent researchers who seek the knowledge that supports meaningful transformative action.

At the heart of the continuum of action research inquiry methods is the assumption that understanding and improving the human condition requires approaches that validate knowledge that comes from within and throughout the system as well as everyone's learning. Action research democratizes the processes of human inquiry as a practice of learning accessible by all adults within systems. Democratizing the process of together making change demands three capacities from the tempered radical: (1) to be an outsider within; (2) to be critical of the status quo while, at the same time, critiquing untempered radical change and (3) to be an advocate both of the status quo when the system is not ripe and of deep change when the system is ready.

For the tempered radical, these capacities come at a cost. These costs include the fact that in truth they have no one single identity and they receive feedback that they are perceived as hypocrites due to the contradiction in their thoughts and actions. In addition, the system fights fiercely to compromise their identity, to move them from outsider to insider and to make them act according to the rules of the system, which may well be at odds with their values and beliefs. The emotional burden associated with this resistance can lead to stress and strain.

Tempered radicals have an uncanny inclination to remain on the margins and at times a contradiction that allows them to span the boundaries of a system to develop new knowledge that may catalyze deeper change. Changes such as personal change, organizational transformation and large-scale social change are the tests of validity that the action research method is at work and affecting a system. Action research methodologies such as Participatory Action Research, Collaborative Developmental Action Inquiry, Appreciative Inquiry, collaborative inquiry and action research provide tempered radicals with a liberating structure that allows them to explore with curiosity the possibilities for change within a system and over time.

In the context of the new normal, a time of great uncertainty and risk, so much of what tempered radicals do is to provoke learning and to seek truth. By taking the risk to act on what they believe and value and being authentic to their identity, with deep respect for their context, they begin new conversations in organizations that over time lead to change. These men and women working within organizations recognize and are committed to the values, beliefs and risks of democracy, which in practice is an endless process of collaborative social inquiry.

THEATRE OF THE OPPRESSED

Theatre of the Oppressed is a genre of theatre devised in the 1970s by the Brazilian director Augusto Boal. This methodological approach, and its associated repertoire of theatre-based methods (sometimes called games, tools or techniques), continues to be used in various parts of the world in research, community development, education, political activist and therapeutic settings. Associated practices include Theatre for Development, Theatre in Schools, Theatre for Living, Applied Theatre and Popular Theatre, among others. It is an approach to theatre that is intentional in its desire to shed light on social issues of oppression and marginalization.

Theatre of the Oppressed was founded on three main techniques: (1) Image Theatre, (2) Invisible Theatre and (3) Forum Theatre. Boal's later works include 'Cops in the Head', 'Rainbow of Desire' and 'Legislative Theatre'. A brief overview of each of these follows.

The first, Image Theatre, is a series of methods that invite participants to create still images with their bodies. Boal claimed that when participants use their bodies instead of their voices to express meaning, these images can sometimes be closer to participants' true feelings, because embodied language can bypass rational defence mechanisms or self-censorship. Image Theatre is often used as a warm-up, in preparation for the more formal theatre productions that follow.

Invisible Theatre is performed in public spaces where people are unaware of the actors in their midst. In his book *Games for Actors and Non-Actors* (2002), Boal lists examples of actors who have sparked heated debates on the theme of sexual harassment in the Paris Metro, the Swedish medical system in a Stockholm ferry boat and the topic of racism in various unsuspecting cafés. When engaging in Invisible Theatre, it is important that the actors rehearse their dialogue and timing privately in advance. Although there is an element of improvisation in that the actors do not know how their audience will respond, the key themes they want to communicate, and the extreme positions on those themes, must be made clear ahead of time. In this form of street theatre, actors are very much dependent on the audience and must be confident that they themselves and the unsuspecting audience members have the ability and the knowledge to address the issues at hand. Unlike other forms of street theatre, however, audience members remain unaware that they were participants in an Invisible Theatre performance and are therefore not left with the impression that they were part of a didactic interaction. Scholars such as Bonnie Burstow have discussed the ethical dimension of this kind of theatre.

Forum Theatre is the technique most frequently associated with Boal. In the forum setting, a play is constructed around pressing issues in the community, and the protagonists are always represented as encountering oppressive situations in which they lose. That is, the plot reaches a negative climax and then ends—no resolution is given. The play is performed once in its entirety and then started afresh a second time. During the second performance, audience members are invited to yell ‘Stop!’ at any time and come on stage to replace a character with whose struggle they identify. When they do come on stage, these audience members try to change the outcome of events so that the protagonist, in changing her or his behaviour, can also change the outcome of the oppressive interaction.

The interactions occurring between audience and actors are mediated by a facilitator, or what Boal traditionally called the ‘Joker’. This Joker explains the protocols of audience engagement and explains, in particular, that the spect-actors should not present magical solutions where people suddenly become kinder human beings; the ideas enacted on stage ought to attempt to truly engage with the complexity of the real-life struggles represented. Boal also cautions the Joker to be aware of evangelical interventions in which audience members who have had no experience with the oppression being depicted come on stage and advise protagonists on how they should proceed. Instead, the interventions can serve as a dress rehearsal for action in the spect-actors’ own

lives and the forum as, ultimately, a venue to rehearse a revolution.

As his methods developed, Boal and others following his lead realized their limitations, particularly in that they could not be transposed, as they were, outside the Latin American countries in which he worked. For example, while working in Europe, Boal discovered forms of oppression he had not previously encountered, such as loneliness, isolation, emptiness and lack of communication, which could not be expressed so easily using Forum Theatre. Through the realization that people had internalized their oppressors, he devised a series of exercises to bring awareness to and ultimately dislodge these self-oppressing voices or ‘Cops in the Head’.

In addition, Forum Theatre is limited in terms of individual agency in the face of oppressive structures (laws, policies, ideologies, etc.). In an attempt to influence these structures, Boal began an experiment in what he termed *Legislative Theatre* upon being elected into the municipal government in Rio de Janeiro. In this capacity, he worked with theatre at the grass-roots level to elicit knowledge about people’s struggles and convert their suggested solutions into law.

As the Theatre of the Oppressed began taking hold around the world through Boal-authorized training centres, it gained a certain level of legitimacy in the eyes of state and provincial funding agencies. This created somewhat of a division amongst theatre artists, where those who do not train in Boal’s methods are generally understood to be applied theatre artists as opposed to Theatre of the Oppressed practitioners.

Theatre of the Oppressed and Popular Education

Theatre of the Oppressed was strongly influenced by popular education, in particular the work of Paulo Freire. Both Freire and Boal advocated for the use of creative methods in literacy education, and as their work spread around the world, various approaches to popular theatre emerged. Freire-informed participatory educators and community development workers initiated several Theatre for Development projects across the African continent in the 1970s, for example, and many such projects continue to this day. For example, Zakes Mda reported several theatre projects in which people were mobilized to take part in national development projects; communities drew connections between local problems and organizations working at national and international levels; genuine, two-way dialogue was established between government and rural villagers; communities were moved to discuss and implement solutions to local problems; solidarity was achieved at village and inter-village levels and, finally,

local forms of cultural expression were validated. He also cautioned that theatre-based approaches can and have been used as propaganda to promote top-down objectives.

Theatre of the Oppressed as an Action-Oriented Approach to Research

Ontologically, Theatre of the Oppressed-based researchers are aligned with a critical, action-oriented position that the purpose of research is not merely to understand or explain reality but to *change* it, in some way, for the better. Epistemological claims include that knowledge can be gleaned from all of the senses, not solely through rational thought, and that new knowledge can be co-created through participatory research processes that involve the people who are experiencing the problem under investigation.

Because they explicitly engage the whole body and the imagination, Theatre of the Oppressed (and arts-based methods in general) can help to access 'other' (and 'othered') knowledge that cannot be so easily accessed via questions and conversation alone. Arts-based methods such as Theatre of the Oppressed serve to holistically integrate intuitive and rational ways of knowing, and as such, using creative media in research offers great potential to surface preconscious or previously unarticulated concerns and desires.

Representation, Knowledge Translation and Theatre of the Oppressed

Through the methods described above, theatre can serve as a means of collecting data. It can also serve as a means of analyzing data and representing results. For example, analysis in Forum Theatre occurs as participants move from Image Theatre into creating a performance based on all the data (stories, images, emotions, visceral experiences) they have gathered through the methods. The performance then serves as a representation of the results. Audience intervention in the performance adds another layer of analysis as members of the community interpret, relate to and take action in relation to the events portrayed on the stage. In this way, presenting research findings through theatre-based methods can serve both a knowledge dissemination and a knowledge translation purpose. Theatre and other alternative means of knowledge dissemination are useful since scientific articles are rarely read outside of academe, nor can they be read by people without the requisite literacy skills or access to scientific databases.

As with any representation, theatre poses a few dilemmas. One such dilemma stems from the question of interpretation. Because research has historically

been concerned with conveying *the* truth, art is sometimes perceived as overly subjective. This dilemma is resolved in part through the argument that we filter the meaning of text through our own experiences in the same way that we filter art. A similar dilemma comes from the possibility that the artist's voice (whichever medium that voice may take, theatre or otherwise) may dominate over that of the participants or that of the essence of the data. This dilemma is addressed through participatory endeavours such as Theatre of the Oppressed, where participants use art to speak for themselves.

In spite of these problematic areas, Elliot Eisner, a strong advocate of arts-based research, offered five reasons to use creative means of representation. First, the arts enlarge our understanding. He suggests that the reason to use a specific tool is because it does a better job than others, and he suggests that the arts are useful in eliciting an empathetic response, which is often required in action-oriented research. Second, he argued, the arts can portray a sense of the particular, and thereby deepen our understanding of the particular, in ways that abstractions cannot. Third, he draws attention to the potential for 'productive ambiguity', suggesting that productive research can serve to complicate our lives by expanding our thinking. Fourth, the arts increase the range of questions addressed by researchers. The arts can give rise to questions from novel perspectives as they engage non-dominant modes of perception and thinking. Finally, he suggests that the arts can activate and cultivate multiple forms of human intelligence. As different researchers inevitably possess different skills, use of the arts can express a broader range of human researcher aptitudes.

Validity

Although diagrams, graphs, charts of various kinds and even some images (photographs, drawings, cartoons) are generally accepted as valid means of representing data within the confines of a text, art alone as a form of scientific representation is still relatively uncommon outside the disciplines of the fine arts. As such, theatre as representation raises a host of questions around validity. This is partly because many people do not have (or do not believe they have) the requisite aesthetic literacy to interpret the validity of the art and partly because the usual means of disseminating knowledge through publication are simply not accommodating. However, since theatre and other arts-based representations often have a powerful effect on their audiences, understanding multiple means of validity becomes increasingly important.

How, then, can theatre-based researchers allow claims to pass as true, valid, justified and substantiated?

Qualitative researchers such as Yvonna Lincoln and Egon Guba have argued that contemporary research attends to multiple, and at times conflicting, criteria for quality, authenticity and validity, including fairness of stakeholder views, ontological and educative authenticity through the raised consciousness of both participants and audience members and catalytic and tactical authenticities through the researchers' ability to prompt action. Transgressive forms of validity also enable social scientists to transgress, reshape and create new ways of relating to and doing research, create heterogeneity of perspectives and make multiple openings for action.

The issue of generalizability in arts-based methodologies is manifested through the relationship between artist and audience. Theatre-based representations are often more concerned with telling the particular stories of participants; however, when readers, audience members or other observers see, hear or feel an aspect of their own reality in the art, they are able to generalize a lesson to a broader context. In this sense, theatre-based representations, like qualitative case studies, can highlight both the threads of individuality and the common experiences of our shared humanity.

Arts-based research in general, and Theatre of the Oppressed in particular, is riddled with questions of aesthetic quality, on which there are competing lines of thinking. In short, one side privileges the quality of participant engagement throughout the process while the other privileges the aesthetic quality of the product. The thought to which a particular researcher or theatre practitioner subscribes is often related to the professional background and training of the person in question, that is, whether or not the person has formal training in the fine arts.

THEOLOGICAL ACTION RESEARCH

Action research is in the business of bringing about change and takes account of people's values and motivations and the value base of organizations. When working with religious groups, theology (articulated religious beliefs) comes into the picture. Professional researchers need to know how to bracket their own value commitments when necessary and negotiate their way around the values of the group. This also holds true for theological beliefs, but it may be more challenging. Theology is obscure to many. Providing a way of handling the specific quality that religious beliefs bring to social action is one reason for having clear procedures for theological action research (TAR).

Many religious groups want to bring a research focus to their mission and practice. They are aware that theological research must examine action and activities, not just the belief system. This is the task of 'practical theology', and it requires proper criteria and procedures and social scientific rigour. But religious groups are right to be wary of underlying assumptions, the risk of a reductionist mindset brought into the research process—even unconsciously—and the religious-theological factor being simply 'sociologized' or 'psychologized'. TAR sets the research process firmly within the lived world of religious faith and theology. As a methodology, it is an adaptation or contextualization of action research.

The model of TAR presented here was developed by a university-based, ecumenical, interdisciplinary research team ARCS (Action Research: Church & Society) on the basis of action research work with 12 Christian outreach initiatives. The team defined TAR as 'a partnership between an insider and an outsider team to undertake research answering theological questions about faithful practice in order to renew both theology and practice in the service of God's mission'.

The main characteristics are as follows:

- a. A particular approach to the experience-reflection-learning-action cycle
- b. An interactive, ‘conversational’ process between the outsider research team and the insider research partners
- c. A specifically theological understanding of the action goal

Theology in the Action-Reflection Cycle

The cycle moves from practice to reflection to practice in an iterative way and as distinct operations, but it is important to note that awareness and understanding are present throughout. The reflection phases intensify but do not exhaust theological awareness, even if these are characteristically seen as the ‘theological moments’. Theology comes to expression thematically in reflection and also in a non-thematic way in experience and action; it is multifaceted and multidimensional. The lived practice of faith already embodies theology.

The ARCS team developed a heuristic scheme (and others are possible) for analyzing and interpreting the research data, which guards the inherently theological nature of this methodology. There are four dimensions—‘the four voices of theology’—the *espoused* and *operant* at the level of practice and the *normative* and *formal* at the reflective level. There is the theology that can be discerned in a group’s adopted mission (*espoused*) and in its actual practice (*operant*) and the theology that is acknowledged as having authority (*normative*—scripture, creeds, liturgical) and that is the fruit of ongoing inquiry (*formal*—the work of the academic theologian). These are not totally discrete streams of theology but ‘places’ where theology is located. They are constantly interacting and interact differently in different confessional traditions.

Partnership, Process and Conversation

The research involves the insider and outsider teams working collaboratively. This generates a range of perspectives that stimulate reflection. The insider team are the practitioners or owners of the practice that is the subject of the research and have a commitment to exploring it with a view to initiating change. Crucially, it is they who determine what the research question is—not the research professionals. The role of the outsider team is to facilitate the research, build the capacity of the insider team and broaden and deepen the reflection by bringing different knowledge and perspectives.

The teams work through a structured process—agreeing on the goals of the research; clarifying the research question; gathering the necessary data; identifying, first separately and then jointly, the emerging theological themes and exploring them; formulating learning points; determining future action and initiating further research. This process unfolds over time—the chronological time it takes for work to be co-ordinated, dates booked and events arranged and the ‘*kairos*’ time that arrives as the insider-outsider dynamic matures: the right moment, the unplanned insight or the conversation that takes off when participants ‘lose track of time’.

Insiders and outsiders have to learn the art of their conversation. They often feel isolated within their own immediate circles—practitioners struggling to relate action to theology and professionals struggling to relate theology to action. TAR as a systematic process establishes relationships and a structured way of having the conversations that bring insight and deepen theological understanding. Misunderstandings can always occur because the process probes differences between belief and action, theory and practice and theology and life. It requires a lively expectation that uncovering such truth points will be creative rather than crushing.

The Action Goal in Theological Action Research

Faith-based social action has direct and immediate purposes, and it also serves the Gospel vision of life. Similarly, TAR has two goals: (1) to stimulate new actions where required and (2) to make openings to a deepened faith dimension. It does this by a research process that enhances theological literacy and, especially, theological fluency. TAR seeks *theologically* imbued change in action.

This deepening of the process of theological reflection on practice within the dynamic frame of action research is at the heart of TAR. Experience shows that as a result new faithful action for God’s mission arises.

THEORIES OF ACTION

The term *theory of action* figures prominently in several literatures, including the philosophy of action and practical reason, sociology, artificial intelligence and policy analysis. This entry focuses on the theory of action approach developed by Chris Argyris and Donald Schön, which has made seminal contributions to professional education, organizational learning and action research. These contributions include the concepts of double-loop learning, theories-in-use, organizational defensive routines and Action Science. They also include practices for helping individuals and organizations improve their ability to double-loop learn and for creating knowledge that can be used for this purpose.

The theory of action approach begins with the premise that human beings design action to achieve intended consequences. These designs can be seen as theories of action of the form 'In situation S to achieve consequence C, do A'. Theories of action include the assumptions under which the actor believes the causal connection to hold and the values that make the intended consequence desirable. A theory of action consists of a complex set of interrelated propositions, a kind of master programme for producing action.

Theories of action are of two kinds. Espoused theories are those that individuals believe they follow and are able to state. Theories-in-use are those that can be inferred from actual behaviour. For example, an individual's espoused theory for handling a disagreement might be 'Get all the issues on the table, and talk it through'. Observing what that individual actually does might lead to inferring the theory-in-use: 'Emphasize facts that support my position, and downplay facts that support the other's position, while presenting myself as an even-handed seeker of truth'. Individuals are usually unaware of discrepancies between their espoused theories and their theories-in-use.

Seeing our behaviour as determined by theories of action directs attention to the knowledge we hold about people, situations and what causes what and also to the reasoning by which we bring our knowledge to bear as we design action in particular situations. But the theory of action approach does not presume that we are consciously aware of all this. Rather, in Schön's phrase, when we act intelligently, the knowing is *in* the action. We rely on tacit knowledge, much as native speakers utter sentences that are grammatically correct without thinking about or even being able to state the rules of grammar that govern their speech. Or, to switch analogies, we are like someone who knows how to ride a bicycle. We can maintain balance, make turns and dodge obstacles without thinking about how we are

doing it. What we are not doing is thinking step by step through a set of rules of the kind that would be necessary if we were to programme a robot to ride the bike. If we tried to do that, we would fall.

What, then, do we gain by understanding behaviour in terms of theories of action? One answer is that it offers a way to reflect on our behaviour in order to become more effective. The idea that there is a design, a theory-in-use, that is governing our behaviour, that it may differ from our espoused theory and that we are probably unaware of discrepancies between the two provides a template for productive reflection. It tells us that we have to begin with the data of our actual behaviour and infer the theory-in-use rather than only introspect on what we were trying to do or what we think we did. Then, we can reconstruct and critically reflect on the assumptions and reasoning embedded in the theory-in-use that we have discovered in our action. We become researchers into our own practice.

Single-Loop and Double-Loop Learning

Theories-in-use are a means for achieving intended consequences. When there is a mismatch between intended and actual consequences, the actor may seek to correct the error by trying a different action strategy while leaving unchanged the governing values, norms and action frames of the theory-in-use. Argyris and Schön called this single-loop learning. For example, a manager who finds that workers are not complying with a directive may shift from the strategy of 'Announce it in the group' to the strategy of 'Call them in one by one and tell them if they don't, they're in trouble', or perhaps the strategy of 'publicly praising those who do it'. These are instances of single-loop learning in the service of getting workers to comply with what the manager has determined is the right thing to do. Double-loop learning, in contrast, occurs when the actor reflects on and alters underlying values, norms or frames and acts accordingly. Double-loop learning might occur if the manager reflects on the possibility that there may be a good reason why the workers are not complying, that perhaps the directive is flawed, and, therefore, inquires into what barriers they are encountering and entertains their suggestions for how to proceed.

Learning processes for double-loop learning differ in important respects from learning processes for single-loop learning. Double-loop learning entails questioning assumptions that may be part of one's sense of competence, identity or code of behaviour. In the above example, the manager may have to reframe the role of manager from 'one who knows, decides and tells' to 'one who engages others to come up with good solutions'. This can be deeply unsettling and may elicit defensive reactions.

Single-loop learning is prevalent, while double-loop learning is rare. A primary concern of the theory of action approach is to enable individuals, groups and organizations to become better at double-loop learning.

The Behavioural World

Human beings live in behavioural worlds created by our own behaviour in interaction with the behaviour of others. For example, if we think we are among friendly people, we are likely to act friendly. Our behaviour elicits more friendly behaviour from others. Over time, friendliness may come to be seen as a characteristic of the community, influencing the behaviour of new arrivals.

Theories-in-use determine behaviour, and therefore, shared features of the theories-in-use of individuals shape the behavioural world. At the same time, the effectiveness of a theory-in-use is partly determined by the behavioural world in which it is situated. Trusting behaviour in a low-trust behavioural world is often punished rather than rewarded. The behavioural world therefore shapes the theories-in-use that individuals come to hold. This interdependence, indeed co-creation, between theories-in-use and behavioural worlds is a point of emphasis in the theory of action approach.

Model I and Model II Theory-In-Use

While espoused theories vary widely, under conditions of embarrassment or threat, almost everyone exhibits some variant of the interpersonal theory-in-use that Argyris and Schön called Model I. The governing values of this theory-in-use are (a) define goals, and try to achieve them; (b) maximize winning, and minimize losing; (c) minimize generating or expressing negative emotion and (d) be rational. The predominant action strategies are to design and manage the environment unilaterally, own and control the task and unilaterally protect self and others. This theory-in-use has predictable consequences for the behavioural world, for learning and for effectiveness. The actor is likely to be seen as defensive, controlling and incongruent. People are unlikely to give each other clear feedback both because doing so would violate the governing values of minimizing negative emotion and unilateral protection and also because they perceive each other as not open to learning. Therefore, actors remain unaware of their incongruence and the impact of their behaviour. It is rare for people to reflect on their underlying assumptions. Learning tends to be single loop, not double loop, which leads to decreasing long-term effectiveness.

Argyris and Schön developed an alternative theory-in-use, Model II, with the governing values of valid information, free and informed choice and internal commitment. The predominant action strategies are to define and

control tasks jointly, to make one's reasoning explicit and testable and to encourage inquiry. The consequences of Model II are that the actor is seen as minimally defensive, reasoning is publicly tested and learning-oriented norms develop. These conditions favour double-loop learning as well as single-loop learning. Problem-solving and decision-making are more effective, especially for difficult problems.

Most people readily espouse Model II, except for situations requiring unilateral control, such as protecting young children from risky behaviour. But most are unable to produce it as theory-in-use, especially under difficult conditions, and are unaware of this limitation.

Organizational Theories of Action

Organizations and their subunits can be seen as having theories of action, both espoused theories and theories-in-use. For example, an espoused theory in one organization was that there is no preset budget for bonuses; if every employee performed at a high level, they could all get large bonuses. But in practice, there was a target number for the total bonus pool, although it was not published. When bonus recommendations exceeded this number, they were returned to the individual departments to be reworked. So the theory-in-use was to set a budget for bonuses, to deny that this was the case and to enforce it by requiring resubmissions. We can speak of this as *organizational* theory-in-use because the individuals involved were acting in their capacity as agents of the organization—as a finance manager, as an executive approving the budget and so on—and because it continued even as different individuals came to hold each role.

The instrumental theory-in-use of an organization includes its task system, processes and procedures and norms for performance. It is enormously complex, and some parts may be inconsistent with others. As the organization's environment changes, so must its theory-in-use, or its performance will deteriorate. Often, these changes involve particular action strategies or procedures, for example, increasing or decreasing production, correcting defects or changing advertising campaigns. Making such changes requires organizational single-loop learning. Some changes, however, involve governing values, norms and underlying assumptions—the organization must, in some sense, remake itself. These changes require organizational double-loop learning.

Organizational Learning

The theory of action perspective on organizational learning focuses on the process of organizational

inquiry. 'Inquiry' is meant in the sense of John Dewey's theory of inquiry, as a process of thought and action that proceeds from doubt to the resolution of doubt, restoring the flow of action. When members of an organization encounter a problematic situation, they seek to understand what is causing it and what they or others in the organization can do to make it better. They inquire on behalf of the organization. If their inquiry leads to changes in the behaviour of people acting in their capacity as agents of the organization, it changes organizational theory-in-use, and we can say that organizational learning has occurred.

Putting organizational inquiry at the centre of organizational learning directs attention to the quality of that inquiry and the factors that influence it. People may be more or less aware of data relevant to the inquiry that resides in other parts of the organization. They may have difficulty talking openly with people in other departments because of inter-group rivalries. They may be reluctant to give a full account of their findings to superiors because of possible repercussions. Factors like these inhibit organizational learning.

Organizational inquiry, as a form of organizational action, is governed by organizational theory-in-use. We can distinguish between the organization's instrumental theory-in-use (how it designs and produces products, sets prices, organizes the sales force and so on) and its theory-in-use for the process of organizational inquiry. We can further distinguish between single-loop and double-loop learning in each of these domains. Of particular interest in the theory of action approach is double-loop learning in the theory-in-use for organizational inquiry, because this increases the capability for double-loop learning in the organization's instrumental theory-in-use.

Organizational Learning Systems

An organization's learning system is formed by the behavioural world that grows around the structure, information network and incentive systems of the organization. The behavioural world includes norms and expectations that affect organizational inquiry such that, for example, some issues are treated as 'undiscussable' or discussion is largely about scoring points or avoiding blame.

As noted earlier, individual theories-in-use and behavioural worlds are interdependent. The theory of organizational learning developed by Argyris and Schön describes how individuals with Model I theories-in-use, acting as members of an organization, create a limited learning system, designated O-I ('O' for 'organization'). An O-I learning system is characterized by dysfunctional group and inter-group dynamics, undiscussable issues and the proliferation of

organizational defensive routines. These factors reinforce Model I theories-in-use.

The preferred entry point for changing these dynamics is the theories-in-use of senior leaders in the organization. Changes in structure, incentives and policies can be helpful but are unlikely to achieve their intended effects in a sustained way unless there is change in the theories-in-use of the people whose behaviour shapes the behavioural world. The reason for starting with senior leaders is that changes in their behaviour are often a precondition for others to use new behaviour and also because they are better positioned to alter organizational factors that otherwise inhibit change. It is also necessary to help people at the next levels to see their responsibility for contributing to the behavioural world and to learn to change their behaviour. As members of the organization develop skill in Model II theory-in-use, the learning system of the organization shifts towards what Argyris and Schön described as Model O-II.

Intervention and Research

The theory of action approach developed out of the long experience of its founders as interventionists, educators, consultants as well as university-based scholars. Argyris was involved in the early years of laboratory education (T-groups) and conducted some of the first studies of increasing organizational effectiveness through laboratory education with intact leadership teams. Schön founded and led consulting organizations in technological innovation and social research before joining the MIT faculty. In his 1970 book *Intervention Theory and Method*, Argyris proposed that the primary tasks of the interventionist were to create conditions for valid information, free choice and internal commitment. When Argyris and Schön published the first statement of the theory of action approach in 1974, these showed up as the governing values of Model II theory-in-use. It was this history of involvement in helping organizations change that led to the emphasis in the theory of action approach on altering the defensive patterns in the organizational behavioural world that inhibit learning and change.

To create knowledge that is useful for practice, researchers and practitioners should join in collaborative action research. The role of the researcher is partly to understand and describe what practitioners do as they inquire into problematic situations and strive to make organizations more effective. But the action research role also includes intervention and coaching to help practitioners go beyond what they already know how to do and to study what then happens. This means that the researcher is also a practitioner and must develop the requisite skill. From the perspective of the theory of action approach, this means reflecting on one's own

theory-in-use and becoming capable of producing Model II responses in the face of defensive patterns embedded in the behavioural world of the client system.

THIRD PERSON ACTION RESEARCH

Third person action research—as distinct from first and second person action research—involves several issues. In this entry, third person activities are taken to refer to processes between people who do not have direct contact with each other. This entry focuses on the myriad challenges posed by third person inquiry and on the possibilities it presents in terms of action research's broader contribution at societal, systemic levels. It also exemplifies some contemporary attempts at third person work.

Although the originators of action research, such as Kurt Lewin, were preoccupied with broadly framed social issues, not least anti-authoritarianism and democracy, their main approach was the utilization of face-to-face groups, where the researchers are either themselves members of the group or work in close contact with it. Against this background, moving beyond the group to reach a wider audience and promote change within, say, large organizations, regions and societies represents a challenge. Various responses have been proposed. The most conventional is to present the experiences from the face-to-face project in a text and expect

the text to diffuse the message. Another possibility is to repeat the project a number of times until a 'critical mass' is reached. A third is to organize the project as a large-scale intervention in the first place, where many people participate in a mass meeting, open inquiry or festival. Sometimes this works well and ensures a broad anchoring through one sweeping move. There are, however, problems: These events are difficult to organize and, as such, tend to be stand-alone events with little 'before' or 'after'. Furthermore, although many people are present, there are generally differences between them: Some are 'on stage', while others constitute an audience. A fourth option is to work with managers and leaders and expect them to transmit the message to those they lead. A fifth is to perform the initial project with units that exist within social contexts—such as networks—which can carry the message further. These are just some examples. Each one can take many different shapes, in addition to which they can be combined in various ways. They can all be strengthened through training and education. They have all been tried, and all can claim advances under certain circumstances. There is, however, no specific approach, or combination of approaches, that functions under all circumstances.

Whatever strategy is chosen, the products of action research have to be fed into more broadly framed processes. While research, under the influence of René Descartes and his successors, has seen the objective observer and disinterested bearer of truth as the foundation for research and, consequently, sought to maximize the distance to other actors, action research has from the beginning departed from this perspective: Research exists within the world, in multiplex relationships to other actors. Research has access to the same channels of influence as all other social phenomena, and since there are numerous sources and means through which society is constituted, there are also numerous channels through which action research can reach out beyond its own immediate context. In this sense, third person inquiry, strategy and process can be identified as the active use of all channels of influence society offers, which go beyond a demand for face-to-face contact. From this perspective, it is not participation in society-level discourses that is the challenge; rather, it is to identify the specific contributions which action research can offer *within* specific kinds of discourse. What is it that action research can contribute that cannot be contributed by others?

Action Research's Contribution at the Third Person Level

Even in action research, it is common to argue that what is produced is knowledge. A similar claim, however, is made by all other forms of research. Insofar as action

research produces something that is unique, the uniqueness must have to do with the *way* in which the knowledge is produced. There are two things that are unique to action research settings: first, the participation of the potential users of the knowledge directly in the generation of the knowledge and, second, the possibility of linking the concepts or propositions through which the knowledge is formally expressed directly to observable behaviour.

For example, in general discourse, the notion of 'trust' is a word linked to other words. In an action research setting, it refers to, in addition, observable forms of behaviour between specific people. From the perspective of understanding the relationship between second and third person discourses, it is the second alternative that emerges as the most important. *The unique characteristic of action research is the creation of situations where words can be systematically confronted with behaviour.* On an abstract level, a concept like trust can mean an almost endless number of different things. When the notion of trust is used in a specific situation where the issue is not only to apply the word but also to demonstrate its meaning through specific forms of behaviour, the options shrink radically. It is like sending the word through a washing machine: When the process is over, the concept is cleaned of a lot of mud that had become associated with it. When the word is again fed into society-level discourse, it has become more powerful through an improved ability to distinguish between real trust and manipulative trust. From this perspective, the role of action research in third person conversations is to feed behavioural understandings of concepts—acquired in second person processes—into the third person discourses.

If we look at some of the major action research projects that have occurred over the years, we see that this is just the kind of function they have had. While the projects of Lewin and associates on issues like authoritarianism, democracy and participation were not repeated, or even investigated with reference to their direct impact beyond the experimental sites, they came to influence more broadly framed discourses on democracy through pointing out specific behavioural aspects of democracy, such as the relationships between leaders and members in ordinary, everyday organizations, like youth clubs. The same pertains to the field experiments with autonomy in work of the 1960s and 1970s. By the end of the 1970s, the wave of experiments had generally died out; what had not died out, however, was the need to link ideas like democracy and learning in work to specific forms of organization. A number of action research projects in association with Majority World aid programmes have laid bare the need for local mobilization and loaded the notion of Third World aid

with criteria for such mobilization. There are many further examples.

Above, the discourses in which action research takes part have been divided into two categories: (1) those that occur in face-to-face contexts and (2) those that occur on the level of society in general. The discourse formations of a modern society are far more complex. In addition to those that occur within the context of the local projects, there are discourses on a number of levels: the organization, the community, the network, the region, the nation and the global, just to mention some examples. To promote development and change, it is often necessary to participate in a number of these. This may look like a very demanding task for research, not least since each discourse formation has characteristics of its own, posing different demands concerning what contributions are relevant and how they need to be expressed. On the other hand, in all societies there will, at each and every point in time, be a number of such discourse formations in operation. Research will not have to construct them all from scratch, but can join the existing ones. The challenge for action research will more often be to change the existing discourses than to create wholly new ones.

Efforts to create change on the level of society will, even when a number of discourse formations are involved, take time. It will seldom be sufficient to back such changes with one, two or even a handful of local projects. Their ability to sustain meanings will diminish over time; competing events will emerge, and important conditions will change. There is a need for a certain rate of renewal of projects to provide new inputs into the broader discourses. The new projects will almost never be direct replications of the previous ones; new conditions and challenges will demand new strategies and new processes.

A further concern is where they should occur. In programmes to promote participation and learning in work in Scandinavia, it has turned out to be an advantage if projects can be spread out geographically to involve new actors continuously. This will also ensure that they occur within different formations on levels such as the network, the cluster and the region. In this way, each formation is subject to direct inputs from within its own domain. These programmes also demonstrate that in building working life in whole nations—even small ones—on notions such as participation, autonomy and learning, the activities need to become permanent. Instead of sporadic inputs into more or less suitable existing discourse formations, there is a need to make the inputs from local projects continuous and to put effort into the construction of discourse formations that are particularly geared to the understanding and use of this kind of input. To achieve this, the programmes are constructed in co-operation between public authorities,

research councils and labour market parties and build on establishing partnerships of various types on regional and similar levels and on producing an ongoing stream of projects throughout the country.

Manifestations of Third Person Inquiry

Discourse formations with a capacity for linking local experiences to society-level processes are sometimes referred to by the terms *development organization*, *Development Coalition* and *social movement*. They extend the idea of large-scale events but with more consideration of the issue of time. Development organization is used to emphasize the point that the kind of organization needed to develop and diffuse change generally differs from the kind of organization needed to handle ongoing production. *Development Coalition* can refer to any kind of network, community or organization; the point is to emphasize that various forms of co-operation are not the result of naturalist forces but of conscious human intentions. The notion of social movement indicates that efforts to achieve broad change do not function through creating identical developments in a large number of places but developments that have some common goals but otherwise show a number of differences conditioned by, for instance, differences in local conditions.

What characterizes the above is a joint interest from a substantial number of people in improvements within an area, in combination with a willingness to actually become engaged together in the improvement process. Today, this seems to be the main approach to the challenges associated with reaching out in society. Projects pertaining to, say, Majority World aid programmes, democracy in work and the status of women will always occur within a context. This context will consist of other researchers interested in the same topic, of various groups of concerned people, of organizations and public agencies working within the area and more. They will often constitute a scattered landscape rather than a co-ordinated social movement.

There will, however, always be some elements of links and relationships present, and there will generally be possibilities for strengthening these elements and activating new ones so that the notion of social movement can be approached. Looking at how action researchers actually function in their daily work, this is very often what they do. Along with project work, there are not only written texts but the active use of other media as well, including meetings and discussions, efforts to convince other actors, alliances with like-minded actors and so on. The notion of spreading research knowledge through social movements, consequently, does not constitute a break with everyday activities but a continuation of them. Furthermore,

even in its face-to-face form, action research deals with, and specializes in, process issues: in how to organize actors, create sustainable developments and mobilize actors around common causes. Complete success in the form of world movements is not common and is difficult to achieve. However, a complete lack of success is not common either. In most cases, action research has some kind and degree of impact, often without itself being fully aware of how far and deep this impact may go.

Recognizing these points, there are some examples of systematic efforts to see to what extent an increase in impacts can be achieved. One example is found in the workplace development programmes unfolding in Scandinavia: Currently existing primarily in Finland and Norway, the programmes are anchored in collaboration between the labour market parties and the political authorities characterizing 'the Scandinavian model'. Generally, using a public agency as the executive body—in Finland a state agency for the promotion of innovation, in Norway the national research council—the central actors form the programme level. The purpose of the programme is to promote projects but within a specific institutional framework. At the same time, as all the projects must fall within the general framework, the programmes have a distributive profile in the sense that they initiate a substantial number of projects spread all over the country.

In the initial phase, each project is limited: It may, for instance, include three to five organizations or even one single organization, provided that it has a complex internal structure, and some researchers in collaboration. This pattern allows for face-to-face contacts between researchers and the organizations involved—at the same time as it makes organizations accustomed to working with other organizations and researchers accustomed to focusing on inter-organizational relationships. Each combination of organizations and researchers can be called a node.

If the nodes are successful in terms of advances, they will be able to pull in further user organizations to provide the foundations for networks, or clusters, of organizations. The new members generally come from the near environment and are recruited not only on the basis of the results achieved but also on the basis of factors such as mutual recognition and trust.

If a number of networks can be established within a geographical framework, generally a region, the perspective of regional development can be added. At least in Europe, most countries have regional institutions for backing economic development, in particular through innovation. These institutions, often forming regional partnerships, can function as policymakers, in particular through linking networks to each other and through co-ordinating the relationships between the networks,

on the one hand, and various support resources, on the other. If there are parallel developments in a number of regions, one may talk about a social movement as a process intervening between the region and society.

With the notion of social movement at the centre, there emerges a structure with a number of levels: the workplace, the organization, the small group of organizations, the network of organizations, the region, the movement and society—and often, the international world can be added. While the workplace generally allows for close and rich contacts between the actors concerned, this potential is successively thinning out as one moves upwards in the system. There is, however, no radical break point. Participants are exposed simultaneously to face-to-face contexts and more distanced contexts in the sense that all levels are present simultaneously.

This multilevel design for change is based on the assumption that people will not be able to develop shared understandings and joint action outside face-to-face contexts unless they have experience with understanding and acting together in their near environment. Only through being formed in the lifeworld will values like truth, fairness and justice be solidly anchored not only in words but also in behaviour.

The chief contribution of the notion of third person action research is not that it has found some new and hitherto undiscovered method of reaching out broadly in society but that it reaches out broadly without losing its basis in the lifeworld. Third person approaches interact with second and first person ones.

TOULMIN, STEPHEN

Stephen Edelston Toulmin was a London-born philosopher (1933–2009) well known in Europe and the USA. He taught for many years at the University of Chicago and then at the University of Southern California. A Ph.D. in philosophy at Cambridge, his early work focused particularly on Ludwig Wittgenstein. Toulmin authored 22 books on a wide range of subjects.

Toulmin's general significance as a philosopher was broad: the philosophy of science, moral reasoning, the critique of both absolutist logic and Platonism and a synthetic critique of Cartesianism based on a more experiential, human and complex view of the world and his linkage of pragmatic and Aristotelian philosophy through science and technology studies in medical anthropology and action research. An elegant writer, Toulmin had a discerning ethnographic eye and the ability to move back and forth among engagement in concrete, pragmatic and policy questions; the history of ideas and philosophical theory and reasoning. He particularly focused on ethics and moral reasoning through extensive work on the dilemmas of ethical treatment of human subjects in research, in medicine and in organizational research. In this way, he contributed to the revitalization of pragmatic philosophy by combining it with systems theory in his work in science and technology studies.

His general significance to the field of action research resides in his unique combination of pragmatic and linguistic philosophy. Through his connections to the Scandinavian action research networks, particularly those of Bjørn Gustavsen, he became a participant in the evaluation and consolidation of a number of large-scale Norwegian and Swedish action research projects. Gustavsen was working hard to bring the 'linguistic turn' from Wittgenstein into action research, arguing that language games were key to larger goals of creating learning networks of action researchers along which new ideas and practices would diffuse. Toulmin's competence in Wittgenstein's work was indisputable, but he added his detailed familiarity with Aristotelian philosophy and American pragmatism to this mix, work that resulted in the revitalization of pragmatism and particularly a focus on Aristotle's

concept of *phronêsis* or clinical or prudential reasoning in context.

Rather than emphasizing the abstract, theoretical habits of contemporary philosophy, Toulmin used his combination of linguistic philosophy, borrowings from Aristotle and neo-pragmatism to press both philosophers and action researchers to operate differently. For the philosophers, he argued, as he did throughout his career, for direct engagement in messy, empirical struggles on the grounds that philosophy's reasoning tools should be made valuable through application in real-world contexts. For the action researchers, he unsettled the constant tendency of practitioners to eschew theoretical and intellectually defensible reasoning about their projects and merely tell stories. He urged them to take responsibility for and create a language adequate to translating empirical cases into challenges to larger understandings about modernity, social democracy and the welfare state. Thus, he issued a challenge to both philosophers and action researchers to meet on a middle ground between cases and abstract theory and build an enriched understanding of both.

Toulmin's work was part of a significant revival of interest in action research in the work of Aristotle, and it is now part of the core discourse of the field of action research. A major publication in this area was Bent Flyvbjerg's book, *Making Social Science Matter*, which gained attention for the Aristotelian distinctions between *theoria*, *téchnê* and *phronêsis* and Olav Eikeland's tour de force, *The Ways of Aristotle*, the work of a Ph.D. philosopher with a quarter century of work in action research at the Work Research Institute of Oslo, Norway. As a guide to Aristotle, Eikeland's text is far and away the most comprehensive and complex. He argues that both Toulmin and Flyvbjerg abstract *phronêsis* out of its larger context in Aristotle and make it too easy for the non-expert to assume that *phronêsis* alone should be the basis for action research. Eikeland shows persuasively that all modes of knowing were celebrated and validated in the Aristotelian system and that using *phronêsis* well requires us to develop nuanced understandings and methods based on *theoria* and *téchnê* as well.

Eikeland's pedagogy here is important in making it clear that for action researchers to simply appropriate an Aristotelian term and use it out of context is an unacceptable shortcut to intellectual legitimacy. Rather, as with most complex matters, raising the level of analytical discourse in action research requires good training and significant effort. Toulmin deserves credit for placing the concept of *phronêsis* at the centre of action research's theoretical and methodological debates and getting this productive dialogue going.

TRANSFERABILITY

The transferability of a research finding is the extent to which it can be applied in other contexts and studies. It is thus equivalent to or a replacement for the terms *generalizability* and *external validity*. This entry outlines a brief history of the term and its successors, a discussion of the most important aspects of transferability as it applies to action research and an account of the strategies an action researcher or other researcher can adopt to increase transferability.

Brief History

In the second half of the twentieth century, a shift occurred in discussions of research quality. An earlier tradition of quantitative research persisted, characterized by experimental design and statistical analysis of increasing sophistication. At the same time, discussion of qualitative research rigour increased. Reflecting the growth, *The SAGE Handbook of Qualitative Research* passed through four editions between 1993 and 2011. However, in much of the literature, experimental

designs (i.e. research designs involving careful control of predetermined variables), and especially randomized control trials, were regarded as the research approach to be encouraged. Many governments held similar views: In the USA, the No Child Left Behind Act of 2001 was explicit that only experimental designs counted as quality research and deserved government support.

Initial discussions of qualitative research often used the same terms and concepts as quantitative research, modifying them only as necessary to accommodate the different characteristics of qualitative research. *Generalizability* was the term used to describe the application, in one study or situation, of research findings from a different research study. Yvonna Lincoln was a prominent champion of qualitative methods during the period under discussion. To counter the dominance of quantitative research, she proposed replacing the methodological concepts of quantitative research with different terms. *Transferability* was substituted for *generalizability* and became a term in common use in the qualitative literature and the action research literature.

Later still, there was a move to choose terms that were devised independently rather than being based upon quantitative research concepts. In these later formulations, *transferability* as a label was less in evidence, though still in use by some authors. By the time of the appearance of the 2011 *SAGE Handbook of Qualitative Research*, the concept for Lincoln had become *cumulation*—the cumulative addition to knowledge by each of a number of studies.

Transferability of Action Research

Action research and case study research—all or most action research can be regarded as intervention case study—have both been criticized for a lack of transferability. It has been argued that generalization is not possible from a single case, though that has been disputed. In some current qualitative research, the issue is not regarded as important or relevant. Many qualitative researchers take the constructivist view that reality is not directly knowable. All theory is therefore a construction of unknown relevance to an unknowable reality. On this view, there is no definitive means of distinguishing one construction from another. A much quoted chapter in Guba and Lincoln's 1979 book *Naturalistic Inquiry* is titled 'The Only Generalization Is: There Is No Generalization'. Some action researchers hold a similar constructivist position, and of them, some have accepted that transferability is not possible. An alternative view is more pragmatic: The main aim of action research is to bring about improvement in some social situation. What is important is what works.

Most definitions of action research pay homage to the three goals of participation, practical outcomes and contribution to knowledge. For many action researchers (particularly practitioner researchers), though, emphasis is on local improvement. Transferability is less important. In the index to the 2008 *SAGE Handbook of Action Research*, there is no entry for transferability. In the same index, the term *generalizability* barely appears—three times, each of those referring only to brief mentions in the text. In the action research literature, as in Kurt Lewin's writing, it is learning or knowledge that is transferred. As action research participants strive to improve their situation, they learn from their experience. It is no coincidence that the action research cycle bears a close resemblance to the experiential learning cycle of authors such as David Kolb. For some authors, such as Judy McKay and Peter Marshall, there are two cycles, one for problem-solving and one for research. Learning can occur in each cycle, about the situation and about the process, respectively.

There is much that can be learned and then used elsewhere. Participants learn about different aspects of the situation they are analyzing and improving. As Margareta Hult and Sven-Åke Lennung explain in their review of action research definitions, participants increase their competence in research and problem-solving as they make use of the iterative action research process. Participants may improve their ability to collaborate as they work with each other. External researchers can then apply their now augmented experience to other action research studies. Participants internal to the community or organization can apply their new knowledge to further improve their situation in the future. Whenever some learning has taken place, it can be argued that some form of generalization or transferability has been achieved.

Strategies for Enhancing Transferability

Research quality is an important precursor of transferability. A lack of confidence in the findings of a study inhibits their use elsewhere. An important strategy for achieving both quality and transferability is to pay keen attention to what is happening. The action research cycle of planning, action and critical reflection provides space for such thoughtful attention in the reflective phase, though it is more valuable if practised at all times. If so, it then provides a quality of presence and engagement that some have identified with mindfulness. Donald Schön named it reflection-in-action and argued that it is a key component of how practitioners learn from experience. With mindfulness, a researcher is more likely to notice a surprising event or result and is thereby given an opportunity to develop new insights. To take this further, participants

in a study can be active in seeking out information that appears to contradict present understanding. Experiential learning is often tacit. Reflection and mindfulness throughout each action research cycle help tacit learning to be made explicit, and thus more easily explained and reported and transferred.

Many aspects of research design play their part too: the choice and engagement of participants, the diversity of participants and informants, using literature to test the boundary of application of findings, access to other people with varied points of view, different forms of triangulation and attention to surprise and disconfirmation. These are discussed in more detail below.

Diverse participants, whether deeply engaged as co-researchers or more superficially involved as informants, provide diverse views. The potential for conflict is thereby heightened, and attention to co-operative ways of relating is necessary. But if participants' views can be reconciled through discussion, a deeper understanding of the situation can arise for all. As a shared commitment is built towards common action, the understanding becomes more practical and deeper still.

Diversity aids rigour and transferability in other respects too. The use of varied methods and processes increases the likely relevance of the findings to other settings. Michael Patton, for example, has argued for diversity of data sources (data triangulation), researchers (investigator triangulation), theory (theory triangulation) and methods (methodological triangulation). In his descriptions of developmental evaluation, a form of evaluation very similar to action research, he again encourages diversity in many aspects of research. In addition, several research sites can be included in a single study, or a study may be researched over a long time period. Similarly, generalization from multiple and diverse studies is easier than from a study of a single site.

Drawing on outside sources of information can help action researchers define the boundary within which their findings may apply. Relevant but different literatures can provide part of this. So can communities of practice: networks of people with similar or overlapping interests. Electronic mailing lists can serve a similar purpose. Common in the educational action research literature is the use of a critical friend, a colleague or mentor who challenges all aspects of a study as an aid to more penetrating reflection.

Used separately or collectively, these strategies enhance both the quality and the transferability of research findings. Some authors describe this approach as dialectic. The strategies have in common the use of multiple sources of knowledge or learning that, when compared critically, allow more confidence in the eventual findings. When some or all of these strategies are employed, the participants of the study are helped to enhance their competence at remedying problems

and improving situations. To that extent, transferability has been achieved.

Transferability Beyond the Study

For the study to be of use to others not directly involved, one or other of two possibilities must occur. On the one hand, the results of the study may be applied elsewhere by those engaged in the study in some way. On the other hand, the findings can be communicated, perhaps in the form of books or journal articles, or less formally through word of mouth, to colleagues and others. For many authors, therefore, such communication is one of the defining characteristics of action research.

Robert Stake has coined the term *naturalistic generalization* for one form of transfer. He claims that it is natural for people to make sense of their experience as it happens or as they read about it in case study descriptions or the like. As they do so, they draw upon current events and observations and also upon previous experience and other information that they have acquired. The flexibility of action research allows even partially relevant learning to be applied, perhaps crudely at first and then with increasing refinement through the trial and error of the cyclic action research process. Stake further suggests, therefore, that it can be left to the reader, listener or observer to decide, naturally, when and what generalization is possible.

A contrary view, as mentioned earlier, is that transferability is difficult. Its feasibility depends upon the similarity between the original source and the situation that is to be the target of the transfer of learning. Only by specifying the salient features of the source can a writer facilitate use of the findings by a reader. Deciding which features are salient then becomes an important choice.

At this point, the different interests of academics and practitioners come into play. Academics are more likely to prefer tightly specified theories that identify causal links between defined variables, even though the cause is often ambiguous in complex situations. Practitioners, on the other hand, are more interested in knowing what they can do to achieve certain outcomes.

TRANSFORMATIVE LEARNING

The term *transformative learning* (commonly known as TL) is an approach to adult learning and education that is embedded within the behavioural sciences, a collective term for a number of disciplines that focus on the study of human behaviour. Emanating from the work of Jack Mezirow, who takes a cognitive rational approach building on constructivist assumptions, it explores how adult learners integrate new learning with their existing knowledge and experiences. In other words, we build and integrate new and revised interpretations of the meaning of our experience, validating it through interaction and communication with others. The end goal of TL is the achievement of greater personal autonomy and independence. There is a special emphasis on the individual as a rational constructor of knowledge, where meaning making happens in a logical and thoughtful manner. The learner works through experiences that challenge his or her tacit, taken-for-granted assumptions, beliefs, values and expectations. The learners renew themselves through envisioning their future and structuring their meaning perspectives appropriately, and as a result they become more open, transparent, flexible, authentic and capable of change. The teacher's role involves taking a consensual approach to teaching, with an emphasis on the centrality of experience, critical reflection and rational discourse. This entry discusses the history and characteristics of TL, in addition to the key concepts of TL, plus TL research and action research.

History of TL

TL and in particular *perspective transformation* as a concept were introduced into the field of adult education in 1978 by Mezirow. The idea drew attention to a critical dimension of learning in adulthood that enables us to recognize and reassess the structure of our assumptions and expectations. Influences include Jürgen Habermas' three kinds of knowledge, Paulo Freire's 'conscientization', Thomas Kuhn's 'paradigms', the concept of 'consciousness raising' in the women's movement, John Dewey's 'prior knowledge and previous experience', Jean Piaget's 'stages of cognitive development', Lev Vygotsky on higher mental functions and the work of the psychiatrist Roger Gould.

The origins of TL theory lie in a national study sponsored by the US Department of Education in the late 1970s. It looked at 83 women returning to college in 12 different re-entry programmes. The research results led Mezirow to posit a theory of adult development, which he called perspective transformation. He focused on the changes in role and self-concepts (perspective transformations) that these women experienced as a result of participating in the respective programmes and the process in which they recognized and reframed their culturally induced dependency and role relationships. Mezirow was interested in the ways in which a person's past (psycho-cultural assumptions) constrains or filters perceptions of the self and relationships with others.

Over the following 10 years, education was incorporated as a process in fostering critical self-appraisal—particularly when linked to self-directed learning. Meaning perspectives were defined as a web of cultural and psychological assumptions, and meaning schemes as the rules and expectations that govern our lives. By 1991, TL was well established within adult education literature, with a strong emphasis on critical reflection and critical self-reflection. It was criticized for being too rational and ignoring the role of symbols, intuition and images in learning, while also neglecting issues to do with social action, power and cultural contexts. Mezirow invited and encouraged critiques of his work, hoping that through engagement with the community of educators interested in TL, the theory would continue to evolve. In 2000, Mezirow acknowledged the importance of the affective, emotional and social contexts of TL and introduced some new terminology. He suggested that the frames of reference which we use to make sense of the world around us have two aspects: (1) a habit of mind and (2) a point of view. Habits of mind are the deeply embedded routines or predispositions that we use to interpret experience, usually expressed as a point of view. TL theory and

writing have evolved over the past 36 years into a complex and comprehensive theory of how adult learning changes the way people think about themselves and the world. A TL movement has developed in North American adult education, with International Conferences on Transformative Learning held since 1998, and the *Journal of Transformative Education* was established in 2003. The origins and development of the TL body of knowledge have been critiqued, examined and further developed predominantly within the field of adult education. This has provided a forum for the continued detailed analysis of TL theory—contributing to a multidisciplinary body of literature and community of practice.

Characteristics of TL

TL theory offers a powerful model for understanding how adult learners cope with the complex demands and conflicts of life. While there are many characteristics of TL, the central ones emphasize adult learning as a process of making meaning out of our experiences and of questioning our assumptions based on prior experience. Our expectations—that is, what we expect to happen—are based on what has happened in the past; they are the product of our experiences. It is these expectations that are called into question during the TL process. Mezirow argues that it is only in adulthood that people develop the reflective judgement necessary to assess their own reasoning about their habitual expectations. Therefore, self-concept is as relevant to TL as it is to adult learning in general. By definition, TL leads to a changed self-perception.

TL is said to occur when individuals experience changes in their thinking that lead to new world views and new perspectives on their personal and professional lives. When the right circumstances occur, TL enables the individual to redevelop existing frames of reference (or points of view), which then become more inclusive, discriminating, self-reflective and integrative of experience.

Mezirow describes defined stages in the TL cycle that include the need for the following:

1. A catalyst for change (disorienting dilemma) that has to occur
2. Critical reflection involving self-examination that acknowledges one’s feelings
3. Consideration of the assumptions being held by the individual
4. A recognition that one’s discontent or destabilization often walk hand in hand with the experience of transformation
5. Exploring one’s options for new roles, relationships and action
6. Planning a course of action
7. Acquiring the knowledge and skills essential for implementing the newly formed plan
8. Testing and provisionally trying out the new roles, relationships or actions
9. Building competence and self-confidence in the new roles and relationships
10. Reintegration of the persons back into their lives, taking on board the changed conditions that are necessary in order to support the new perspectives they have developed through the TL experiences

Mezirow begins with the assumption that everyone has constructions of reality or ‘perspectives’ that are dependent on reinforcement from various sources in the world around them. His seven stages in the TL cycle can be broken down into four distinct parts which tend to operate as a learning process with a sequential flow, namely, (1) experience, (2) alienation, (3) reframing and (4) reintegration (see Figure 1).

Experience of a Disorientating Dilemma (Stage 1)

The TL process begins with an experience, but not just any experience. It is an experience in which

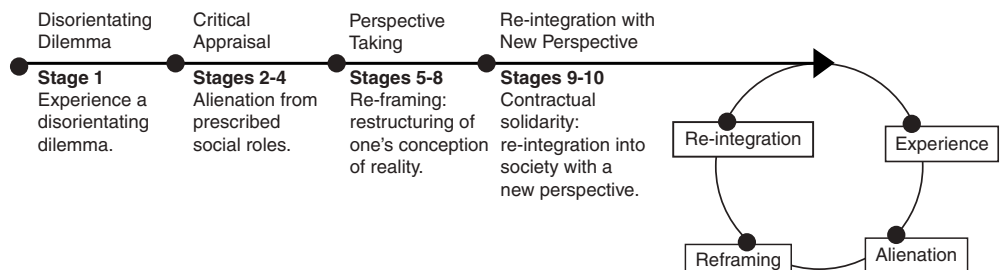

Figure 1 Iterative Nature of the Transformation Cycle

individuals' perspectives (current assumptions and beliefs) are not in harmony with the world around them. As a result, they experience a disorientating event—a critical incident where their construction of reality is challenged or not reinforced by sources around them. Their sense of well-being is damaged or changed in some way. The catalyst for change (critical incident) that has to occur is usually a major personal life event.

Alienation From Prescribed Social Roles (Stages 2–4)

The individuals concerned critically examine the assumptions and beliefs that have led to their interpretation of this experience. In colloquial language, they speak about 'questioning themselves' or 'taking time out to think about things again in a different light'. They experience 'disjuncture', a feeling of not being in harmony with one's knowledge of the world in which one is acting and with the emotions being experienced. The adult becomes ill at ease or disoriented. This experienced lack of accord between the external world and the internal biographical interests or knowledge can create such a feeling of disorientation that adults begin a process of re-evaluating their previously unexamined values, beliefs and understanding. At this stage, individuals engage in critical appraisal—examining or recognizing their feelings of fear, euphoria or anger—consider their assumptions and recognize their discontent and sense of destabilization. Once the individuals have critically examined the assumptions and beliefs that have structured their experience, they may find that it causes them to revise their assumptions about themselves and others. This can be up to and including the revision of the very basis of their previous assumptions—to the extent that they have been changed completely.

Reframing One's Conception of Reality (Stages 5–6)

Reframing occurs when adults search for a way to add new knowledge and experiences to what they already know. Adjusting or changing their previous assumptions, they begin to move towards new meanings or perspectives. External and internal biographical interests and knowledge begin to adjust in such a manner that it causes a transformation in these perspectives—leading to a new meaning being created by the individuals, which at this stage is very subjective, fluid and changeable. They are in a state of 'flux', which is resolved by testing whether the new meaning created is true or authentic. From this point, they move to explore their options for new roles, relationships and actions—planning a course of action and determining what knowledge and skills are required for implementing the plans. To arrive at the best possible judgement, the person will actively seek out opinions

of others, including opinions that will challenge the status quo. When engaging in this discourse, they are actively searching for a common understanding, an assessment of the justification for an understanding or a belief. This discourse is not about debate or conflict; it is a focus on finding agreement in order to build a new understanding. It can happen in a one-to-one context, in groups and in formal educational settings. It is important to move adults from an argumentative mindset to one of empathic understanding of others' lives. Having considered what new knowledge and skills are essential, the adults test out their planned new roles, relationships or actions—thereby increasing their self-confidence and competence.

Reintegration With the New Perspective (Stage 7)

The result of this experience, critical appraisal and reflective discourse is taking action, which might happen immediately, be delayed or be the reaffirmation of an existing pattern of action. The individuals experience a reconnection as they reintegrate into society with new or changed perspectives. Their world is back in balance again when they have taken on board the changed conditions that are necessary to support the new perspectives they have developed through the TL experience.

Key Features of TL

The following are some of the key features of a TL approach to adult learning and education.

Meaning Perspectives

These are a complex network of assumptions and expectations through which a person filters his or her experiences and determines how he or she sees the world. These networks have two dimensions: (1) a habit of mind and (2) the resulting point of view.

Habits of Mind

These are broad outlooks or dispositions that are used to interpret experience; they are usually expressed as points of view or opinion. Individuals' points of view comprise a cluster of meaning schemes that are habitual, general rules for interpreting experiences. In short, it's how they think or have learned to think about things, including deeply held assimilated ways of knowing, believing and feeling. Some of these include unquestioned or unexamined beliefs, as well as prejudices, distortions and stereotypes. Simply put, a habit of mind is a way of seeing the world based on one's background, experience, culture and personality. All six are interdependent and interrelated—overlapping and influencing one another (see Table 1).

<i>Epistemic</i>	<i>Aesthetic</i>
Knowledge, how we acquire it and how we use it; the way we learn, learning styles and preferences	Values, attitudes and tastes; judgements and standards of beauty, art, music and fiction
<i>Sociolinguistic</i>	<i>Moral-Ethical</i>
Social norms and cultural expectations; the way we use language, for example, ‘IT speak’, and our roles in society—woman, teacher, father, child—all define how we should behave	Conscience and morality, how we define good and evil and how we act on our views of goodness and see ourselves responsible for advocating for justice in the world
<i>Psychological</i>	<i>Philosophical</i>
Who we are and how we see ourselves—our self-concept, needs, inhibitions, motivations, anxieties, fears and personality	Our world view, philosophy or religious doctrine determines our social, political and economic aspects of living

Table 1 *Habits of Mind*

Perspective Transformation

These start from the assumption that everyone has constructions of reality that are dependent on reinforcement from various sources in the world around them. Maintaining a meaning perspective is safe. They change or are transformed when individuals’ perspectives are not in harmony with the world around them. In this state of disjuncture, the person’s construction of reality will be transformed when one changes a belief or attitude (a meaning scheme) or experiences a revolution of an entire perspective (habit of mind). There is a recursive and evolving nature to the TL process that is best explained as a constant process of constructing and integrating new or revised interpretations of the meaning of one’s experience. Learning occurs when an individual encounters an alternative perspective. This was originally seen as a single disorientating event (epochal), but it has since been acknowledged that it could also be a gradual cumulative process (incremental) of everyday events.

Conditions for TL

The most important concepts to emerge from extant research on the conditions that support TL include (a) life experience, (b) the nature of critical reflection, (c) rational discourse and (d) action (see Figure 2):

- a. Life experience or disorientating dilemma is the starting point for the TL process, but not just any experience. It has to be a critical incident that acts as a catalyst for change where current assumptions and beliefs are challenged or not reinforced by sources around the learner. A diminished sense of well-being is experienced

as a result of a *disorientating dilemma*, which can lead to the person concerned critically examining the assumptions and beliefs that have led to his or her interpretation of this experience.

- b. Critical reflection and critical self-reflection are central to TL. Three kinds of reflection are identified: content, process and premise. Content and process reflection ask the questions ‘What is the problem?’ and ‘How did it come to be a problem?’, and this may lead to transformation of specific assumptions and

Figure 2 *Conditions for a Transformative Learning Environment*

beliefs. Premise reflection, challenging the very basis of the problem or issue, has the potential to promote transformation in habits of mind.

- c. To arrive at the best possible judgement, individuals will actively seek out opinions from others, including opinions that will challenge the status quo. When engaging in this reflective discourse, they are actively searching for a common understanding—an assessment of the justification for an understanding or a belief.
- d. The result of this disorientating dilemma or experience, critical reflection and reflective discourse is taking action. This can happen immediately, be delayed or be the reaffirmation of an existing pattern of action. The range of activity can be from making a decision about something to actively engaging in events or doing things

Types of Learning

Not all learning is transformational. This does not imply that other learning is not highly significant or an important experience for the learner. Individuals can add to their existing meaning schemes or add new meaning schemes to their storehouse of knowledge that are highly significant and a source of achievement and success for them. TL theory identifies four ways in which learning occurs: (1) elaborating existing frames of reference, (2) learning new frames of reference, (3) transforming points of view and (4) transforming habits of mind.

TL Research and Action Research

Three major reviews of TL research have been conducted covering the periods 1978–98, 1999–2005 and 2006–10. The subdivision of the body of knowledge, based on ‘locus of learning’, provides a useful way to identify the underlying assumptions within these varied perspectives (see Table 2).

<i>Individualistic</i>	<i>Sociocultural</i>
Psycho-critical	Social-emancipatory
Psycho-developmental	Cultural-spiritual
Psychoanalytical	Race-centric
	Planetary

Table 2 *Approaches to Transformative Learning*

SOURCES: Cagney, A. G. (2011). *Finding the red thread: The role of the learning space in transformative learning in executive education* (Unpublished doctoral thesis). Trinity College Dublin, Dublin, Ireland; adapted from Taylor, E. W. (2007). An update of transformative learning theory: A critical review of the empirical research (1999–2005). *International Journal of Lifelong Education*, 26(2), 173–191.

The early-stage (1978–99) research review revealed that TL was found to be effective at capturing the meaning-making process of adult learners, particularly the learning process of paradigmatic shifts. Many of the phases of the transformative process described by Mezirow were confirmed, in addition to the essentiality of critical reflection and the centrality of a disorientating dilemma as a catalyst for change. It also revealed a learning process that needed to give greater attention to the role of context, the varying nature of the catalysts of transformative knowledge, the increased role of other ways of knowing, the importance of relationships and the need to broaden the definitional outcome of a perspective transformation. By the time the second review (1999–2005) was published in 2007, there was less research identifying transformative experiences in different settings and more research about fostering TL and the complex nature of critical reflection, the importance of relationships, the emerging role of difference, the nature of perspective transformation and the role of context. Three broad themes that emerged at the time were as follows: (1) the continued predominance of qualitative research methods in the field, (2) the emergence of action research as a methodology congruent with the nature of TL and (3) a growing trend towards mixed-methods studies. The third review (2006–10) has identified action research, narrative inquiry, autoethnography and case study as the predominant methodologies, with collaborative inquiry and group dialogue research showing promise. Interdisciplinary interest has grown, as evidenced by studies in agriculture or the sciences, archaeology, religious studies, health care, critical media literacy and spirituality. Research conducted outside classroom environments has increased, with further exploration required into what is unique about these settings and their implications for fostering TL. Areas for future TL research include (a) adults in later stages of adulthood, (b) adolescents, (c) exploration of how people make sense of transformative experiences, (d) application of other theoretical frameworks to address the areas of weakness in Mezirow’s dominant perspective (e.g. affective learning, spirituality and power) and (e) emerging insights about the social nature of TL revealed in the constructs of social recognition, social accountability and the significance of relationships.

TL theory in general is about change—dramatic fundamental change in the way individuals see themselves and the world in which they live. This type of learning is more than just adding to what they already know; it is transformative because it shapes individuals in ways that result in changes that both they and others around them can recognize. Described as a shift of consciousness that alters in both a dramatic and a permanent way our ‘being-in-the-world’, it changes *how* we know. It leads to a different kind of thinking

and being that enables individuals to become open to revisiting their interpretations of the meaning of their experience, in turn guiding future action. It is precisely this unique aspect of TL that makes it so congruent with action research.

Action research involves the individual learner in his or her own learning, not only producing better learning but also more valid data on how it actually occurred. When individuals try to change their internal systems of belief and assumption, it often involves variables that cannot be controlled by traditional research methods. Action research is flexible, allowing an experiential approach which goes with the story as it evolves, and involves adult learners in the inquiry process itself. This is one reason why action research has a natural affinity with TL, as it allows the study of how learning and understanding develop in the midst of bringing about personal change and development.

Secondly, TL requires a collaborative, facilitative and reflective interventionist form of research that demands that those involved in the research initiative attend explicitly to their own learning in action, to the dynamics and quality of their engagement with adult learners and to the generation of actionable knowledge. Managing both the highly emotive consequences associated with TL and the learner-centred approach often intrinsic to action research is a challenge within the context of a clearly defined research agenda. The flexible nature of action research can accommodate studies that incorporate research designs that could potentially lead to greater reliability in the identification of essential components like critical reflection and perspective transformation. It offers a way to begin to engage with this type of inquiry while producing research that is rigorous, reflective and relevant. Thirdly, TL provides a pedagogy for classroom teaching that shares similar assumptions and outcomes about teaching for change with action research—the participatory approach, the emphasis on dialogue, the essentiality of a reflective process in learning and the need for action. More longitudinal action research studies could contribute to a more informed practice for fostering TL and an effective method of classroom research.

Action research offers a complementary methodology of working with adult learners as they go through this TL process. It is continuously evolving as it has the capability to adapt and respond to the variety of emerging challenges experienced by individuals, groups, organizations, communities and societies. It can therefore keep pace with the multidisciplinary and evolving nature of TL research and thinking. It involves collaborative research in that it has always espoused research *with* people rather than *on* or *for* them.

TRANSPERSONAL INQUIRY

Transpersonal inquiry, although regarded as a relatively new empirical approach to research, derives from a very long and ancient tradition that has explored the deeper and more subtle aspects of human awareness, experience and action. The term *transpersonal* (in other words, *beyond* personal/ego/self) was first coined in the field of psychology in the early 1970s, with its immediate roots stretching back more than a century in the work of William James, Carl Jung and many others. It is an approach to inquiry that embraces the creative, the spiritual, the subtleties of consciousness and human community, as well as both the normal and the exceptional in human experience. Partly through the work of Peter Reason and John Heron, the transpersonal has become established as a focus within action inquiry, offering an approach to research that is more relevant to a holistic view of human practices and the wider contexts of human action that is committed to the promotion of human flourishing.

A Transpersonal Vision

Rosemarie Anderson and William Braud, in their revised outline of transpersonal inquiry methods (2011), have argued for the pressing need to reclaim science's original vision to promote a global community which would include a 'more-than-human' world. This transformative vision for research would aim to support individual, communal and worldwide transformation by embracing and honouring the full range of the world's wisdom traditions. This calls for an approach to human inquiry that would involve the

reinvention of humanity as a global community, such that people worldwide should become perfectly themselves without any need to imitate each other. The human species cannot survive without diversity. It is through our diversity that we will survive.

It is precisely this vision that resonates with what Reason and Hilary Bradbury offer as a ‘participatory world view’ for action research, which they see as a democratic process that can develop practical knowledge in the search for what is really worthwhile in being human—in other words, research that will identify realistic ways to encourage the flourishing of individuals and their community. Reason and Bradbury’s emphasis upon a participative approach to action research closely aligns with the transpersonal world view.

In Heron’s Co-Operative Inquiry approach to action research, an extended list of ‘special inquiry skills’ has been identified. This includes participative knowing, being present, openness of imagination, emotional competence, non-attachment, self-transcending intentionality, chaos and order, managing unaware projections and authentic collaboration. Such a range of skills is largely supported by an underlying transpersonal level of awareness, which again reinforces the close link between transpersonal inquiry and action inquiry.

Furthermore, the important consequence of equating action research with a participative inquiry approach is the link that is being made to the idea that the essence of transpersonal experience is that it involves the notion of ‘knowing through participation’. This idea of knowing through participation is part of what Jorge Ferrer has called the ‘participatory turn’ in the human sciences, which relates directly to ideas such as ‘participatory consciousness’ (Morris Berman), the ‘participatory mind’ (Henryk Skolimowski), ‘sacred inquiry’ (Peter Reason), ‘participatory reality’, ‘participatory theology’ and a ‘sacred science’ (John Heron).

Ferrer suggests that transpersonal phenomena are really more like someone being at a party, where an individual cannot be said to be having experiences but is participating in the social event. These participations are neither ‘objective’ nor ‘subjective’. As such, they are not anyone’s property but are simply the coming together of certain conditions. Ferrer suggests that this situates transpersonal inquiry more closely to the tradition of spiritual practice, where it is generally accepted that the aim is not to have an experience but to participate in a special state of discernment. Transpersonal phenomena are not to be understood merely in phenomenological terms but rather need to be seen as the consequence of participating in aspects of being that transcend the merely human.

When referring to knowing through participation, there are three points that can usefully be made. Firstly, human thinking, meaning making and action

all spontaneously arise from the creative embodied interactions of the individual person with his or her environment. Secondly, any method of research concerned with authentic human practice will necessarily need to focus at some point on transpersonal/spiritual experience, which must entail a participatory approach to inquiry. Finally, it might be useful to regard the essence of human spirituality as a profound participation in life. Indeed, humans experience life by taking part in it, which may seem obvious, but it does need to be fully explored. Therefore, taken from this perspective, what seems to distinguish the spiritual from other forms of participatory knowing is its authenticity, and any research concerned with authentic participatory practice must take human spirituality (in its widest sense) more seriously.

Methods for Transpersonal Inquiry

The essence of a transpersonal approach to inquiry is that the participatory experience to be studied cannot be forced or coerced into view but can be facilitated by a careful consideration of the optimizing participatory context. These might include, for example, a human inquiry group; a workshop; a meeting, ceremony or ritual practice; a meditative or spiritual practice (e.g. transcendent awareness); an exercise in mindfulness, reflection-in-action and non-ordinary states of consciousness (e.g. dreams, guided fantasy and spontaneous visions); a personal story or a simple person-centred interview, amongst others.

More than any other influence, the field of transpersonal inquiry has been advanced by the publication of two landmark texts by Braud and Anderson (1998, 2011). Together with the major contributions made by Heron and Clark Moustakas, these approaches to inquiry are briefly outlined below.

Braud and Anderson’s Basic Holistic Methods

In chapters by the respective co-authors, Braud and Anderson (1998) consider five different approaches to transpersonal inquiry:

1. *Integral inquiry* (Braud): This approach focuses on an experience with great meaning, affirming the view that human experience is multilevel, complex and transformative. Integral inquiry is therefore multifaceted and pluralistic. There are four basic research questions: (1) the nature of experience, (2) experience conceptualized through history, (3) the triggers of experience and (4) the outcomes/fruits of the experience.

2. *Intuitive inquiry* (Anderson): This is characterized as following the ways of the heart, exploring experience that is complex and subtle and stressing intuition and

altered states of consciousness. It is based on classic hermeneutical understanding as personal and cyclical rather than linear and procedural. Throughout intuitive inquiry, compassion towards the self and others is considered central to understanding.

3. *Organic research* (Jennifer Clements): This uses the fundamental technique of listening to and telling stories, growing out of the researcher's own story, emphasizing the use of the participants' own voices and words. Organic research involves a three-step process: (1) preparation, (2) inspiration and (3) integration.

4. *Transpersonal-phenomenological inquiry* (Ron Valle): This approach offers an explicit focus upon the nature of transpersonal/transcendent awareness. Recognizing the limits of a basic phenomenological methodology (with its focus on the contents of consciousness), it attempts to explore deeper senses of spirituality and self-transformation. It holds that transpersonal awareness is prior to human consciousness in that it is always unavoidably connected to a notion of what is beyond being human.

5. *Inquiry informed by exceptional human experiences* (Rhea White): This approach involves exploring a wide range from the anomalous to exceptional human experience, with a view to honouring other ways of knowing and other realities, with their potential for transformation, for example, dreams (including lucid dreams), hunches, hypnagogia, hallucinations, empathy, extra-sensory perception, out-of-body experience, synchronicity as well as mystical, psychic or near-death encounters and exceptional normal experiences. The emphasis is on not exploiting the subject matter but on empathizing with it.

Heron's Sacred Science

Co-Operative Inquiry and lived inquiry are Heron's basic research tools for his emerging participatory inquiry paradigm, which emphasizes that inquiry into the human condition cannot be done from outside. Heron argues that it is not possible to be outside oneself. And even if we could by some means get outside, we would need to get back inside in order to study ourselves.

In Co-Operative Inquiry, the exclusive roles of researcher and participant are replaced by a co-operative relationship of shared initiative and control. This is not research on people but research in co-operation *with* people.

Co-Operative Inquiry involves two or more people researching a topic through their direct experience of it, using an adaptation of the action research model,

cycling through four steps: (1) agreeing on a focus of inquiry, (2) action, (3) reflection and (4) evaluation, leading to the next cycle.

Moustakas' Heuristic Inquiry

As an approach to self-inquiry, heuristic inquiry is possibly without rival. Heuristic inquiry involves a way of knowing where the researcher must have had a direct, personal encounter with the phenomenon being investigated. The researcher experiences growing self-awareness and self-knowledge, promoted by self-search, self-dialogue and self-discovery. What explicitly becomes the focus of the approach is the transformative effect of the heuristic process on the researcher's own experience. It is the participatory nature of this heuristic inquiry process that relates it to the transpersonal.

Other Approaches to Transpersonal Inquiry

In addition, two other transpersonal approaches are worth briefly mentioning. Valerie Bentz and Jeremy Shapiro have developed what they have called 'mindful inquiry', which combines the methods of phenomenology, hermeneutics, Buddhism and critical social science into an innovative transpersonal approach. And Les Todres has outlined an approach that he calls 'embodied inquiry', which considers the lived body as a primary way of knowing and being, which offers, in turn, a participatory/embodied view on human spirituality.

Current Issues in Transpersonal Inquiry

While the nature of the transpersonal paradigm requires an approach to inquiry that is necessarily somewhat in contrast to other areas of scientific inquiry, it does not need to be seen as any less scientific or empirical than any other area of inquiry. The empirical data may be different, taking the form of subjective experience, discernment and direct knowing. But here it is worth noting something that the transpersonal philosopher Ken Wilber has stressed. In his discussion of transpersonal experiences, he asserts that such experience is repeatable, reproducible and confirmable, which, of course, are the basic requirements of the scientific approach.

Transpersonal research methods are being used widely in the human sciences, although this does involve ways of working with participants using 'methods' which generate data that goes beyond simple verbal accounts of human experience. These can involve visualization, active imagination, meditation, body and sound work and so on, all of which can facilitate human experiences that will require unique ways of recording data and unique forms of data analysis.

Finally, it is worth noting that transpersonal inquiry has generated an innovative range of transpersonal research skills that may be of direct use to action researchers. In addition to those proposed by Heron mentioned earlier, there is also an extensive discussion by Braud and Anderson of matters such as encountering and collecting data, engaging and confronting data, expressing and communicating findings, together with their expanded view of validity, ethical considerations and so on.

TWO-COLUMN TECHNIQUE

The two-column technique is a case method designed to help action researchers and their participants or clients investigate the effects of hidden assumptions on performance and quality of learning. The technique consists of the written recollection of a past conversation along with the unsaid thoughts and feelings experienced at the time. It presumes that the flow and outcomes of conversations are affected as much by the implicit, the hidden and the unsaid as by what is explicitly stated and that exploring the

disjuncture between the two provides powerful learning opportunities.

The technique was first described in Chris Argyris and Donald Schön's seminal book *Theory in Practice*, where it provided a window on the role played by *theories-in-use* (a hypothesized cognitive grammar that governs goal-directed action) in the misunderstanding of social situations and the perpetuation of conversational routines that prevent learning. The method reached a far broader audience with its inclusion in Peter Senge's *The Fifth Discipline* in 1990. Here, the technique was presented as a useful method to explore the sometimes counterproductive role of hidden assumptions in shielding people from their own, and others', underlying thoughts and feelings, thus preventing learning and effective problem-solving.

An example of a two-column case is given in Table 1. Typically, the instructions that accompany the development of the case ask the participant to begin with a one- or two-paragraph description of the situation, usually incorporating a brief synopsis of the history of the problem, the people involved and the participant's role. The writer is also required to briefly describe her strategy: What were her expectations for the interaction? What did she want to achieve? Why and how did she intend to reach those goals?

The writer then completes the case proper. Dividing several pages in half (suggested lengths vary, but two to five pages is typical): The right-hand column contains the recollected dialogue that actually occurred (or, in a projection of a future episode, dialogue that is expected), while the left-hand column contains any unsaid thoughts or feelings that occurred to the writer at the time but for whatever reason remained unstated. Lastly, the participant is asked to list any lingering concerns, puzzles or questions and evaluate whether her outcomes matched her intentions and, if not, how she accounts for the discrepancy.

Working With the Two-Column Case

An action researcher can facilitate participant work on the two-column case in a variety of ways that will depend on the needs of the participants and the purpose of the research engagement, as well as the action researcher's explicit or tacit theories. The merit of the two-column data is that it helps with the exploration of the implicit dimensions of conversations. The role of hidden and untested assumptions, the viability of the overall strategy for the conversation and the social rules that underlie what can and cannot be said (including which emotions are permitted in the discussion) can all be examined and their role in the conversation's outcome(s) made tangible.

Tim Rogers

Description of the situation

I (Maggie) want Li-Na to enrol in a public speaking workshop (my goal for the conversation). I've heard that it is very good. Li-Na is the lead on our team for the project we are working on and must do the key presentations to clients on the approach we are hoping they will endorse. She has been a very poor presenter but appears to be totally unaware of this. It is costing us clients and might end up costing us our jobs. My aim is to help her improve, but I have to handle it carefully. After all, she's my boss!

Unsaid thoughts and feelings
What was said

Me (Maggie): Li-Na is a really lousy presenter; it's amazing she's come so far in her career without having dealt with this. It's up to me to get her to improve, and fast.

How did you feel the presentation went?

Me: Them? I think you didn't demonstrate any of the advantages we offer. At any rate, it's the unprofessional face you present to clients that really hurts us.

Li-Na: As well as can be expected, I don't think they were ready to hear us.

Me: I go?! I only volunteered to make it easier for her to go. She's in complete denial and doesn't understand the gravity of the situation.

Maybe. We might need to really lift our game to get through to clients who aren't ready. You know, to really push through. There's a workshop coming up in mid May at Andersen's that is designed to help us do just that. Maybe we could see if we can both go?

Li-Na: Maybe—our schedule is tight right through to September. Perhaps you go and fill me in.

Me: She looks angry. I took a big risk there and I'm feeling on the spot. I won't be doing this again.

I really think as team lead, you're the one in the spotlight most and so need the cleanest, most up-to-date skills.

Li-Na: I've done dozens of those things. I'm not about to drop the analytics I'm responsible for preparing and go to a workshop.

Sure, just an idea.

Conclusion

I tried to make it easy for her to make an improvement. I honestly think she's resistant. I don't know how to get through to her.

U

UBUNTU

The concept of *ubuntu* is an alternative to individualistic and utilitarian philosophies that tend to dominate in the West. It is a Zulu/Xhosa word, with parallels in many other African languages, which is most directly translated into English as ‘humanness’. Its sense, however, is perhaps best conveyed by the Nguni expression ‘*umuntu ngumuntu ngabantu*’, which means ‘a person is a person through other people’.

The origins of *ubuntu* as a concept can be traced to the Bantu peoples of southern Africa, although the philosophy is now shared across much of the continent. It is perhaps best understood as a social philosophy—based on principles of care and community, harmony and hospitality, respect and responsiveness—that expresses the fundamental interconnectedness of human existence. It has been described as a philosophy of peace and is perhaps best known as a guiding concept of the African Renaissance, spearheaded by post-colonial and post-apartheid leaders in South Africa such as Nelson Mandela, Desmond Tutu and Thabo Mbeki, in which Africans are urged to re-engage with African values. It has been an important concept in the reform of education and public services in post-apartheid South Africa and offered a framework for the Truth and Reconciliation Commission, which bore witness to the injustices of the apartheid era from the perspective of both perpetrators and victims.

Whilst the origins of *ubuntu* are distinctly African, parallels have been drawn with similar concepts in other societies, including the Chinese philosophy of *Jen*, the Filipino philosophy of *Loob* and the Russian concept of *Obschina*. Similar concepts are also illustrated in the writings of certain European philosophers such as Emmanuel Levinas and Paul Ricoeur, although no comparable word exists in the English language.

Archbishop Desmond Tutu has called *ubuntu* ‘the gift that Africa will give the world’ and, along with

others, has called for its wider application well beyond Africa. Former US president Bill Clinton has also been a staunch advocate and promoted it through his foundation as well as in high-profile speeches in the USA and UK. The term has also become well known through its use as the name for an open-source computer operating system and even as a brand of fair-trade cola, although these are not the focus of this article.

Assumptions and Implications

Ubuntu can be considered as both a descriptive account of the value systems that operate across much of sub-Saharan Africa (and hence helpful in understanding and contextualizing research and practice in this part of the world) as well as a normative philosophy of how people should relate to one another (of relevance well beyond Africa). Both perspectives comprise a number of assumptions and implications that are relevant to researchers and practitioners from an action research perspective. Whilst these points are clearly of relevance to those conducting work with and for Africans, they may also offer the potential for reframing the process of research and inquiry elsewhere.

Interdependence

Ubuntu is a relational philosophy; its frequent articulation as ‘I am because we are’ points towards a strongly constructivist ontology in which individuals’ sense of being cannot be detached from the social context in which they find themselves. It highlights the importance of a subjective and emotional appreciation of human experience rather than privileging objectivity and rationality. In terms of research, an *ubuntu* perspective calls for an interpretivist epistemology in which precedence is given to qualitative methods that enable an inductive understanding of how individuals and groups make sense of the world around them. Whilst such an approach is relatively common in the field of action research, it

stands in stark contrast to the positivist paradigm that dominates much social theory and research.

Inclusivity

Ubuntu is collectivist in orientation—expressing the value of collaboration, co-operation and community. It espouses an ethos of care and respect for others and the importance of solidarity in the face of adversity. It is perhaps unsurprising that such an approach has prevailed in a continent that has experienced so much social, political, environmental and economic upheaval, where collective action and mutual assistance have been essential to survival. Whilst some collectivist philosophies have been criticized as oppressive and totalitarian, ubuntu is described as an inclusive approach which calls for dignity and respect in our relationships with others. In research, such an approach would suggest a tendency towards participative and Co-Operative Inquiry, where the researcher develops a close relationship with participants and actively engages them in the design, conduct, interpretation and application of research as co-investigators. It is also well suited to asset-based approaches, such as Appreciative Inquiry, which emphasize the need to recognize and build on strengths rather than focusing on how to resolve weaknesses.

Intersubjectivity

Whilst described as a collectivist philosophy, in practice, the concept of ubuntu is intersubjective in that it focuses on the *relationship* between the individual and the collective, rather than privileging one over the other. Such a perspective may help researchers and practitioners address the ‘structure-agency debate’ by indicating that it is not a case of either/or but the manner in which independent agents interact with more enduring social structures that matters. The intersubjective dimension of ubuntu is further highlighted through calls for greater inclusion of indigenous knowledge in education and organizational practice, and even the incorporation of spirituality. From this perspective, a detailed appreciation of context and how it influences the subjective realities of different parties is an essential part of the knowledge creation process.

Limitations and Critique

Whilst Africans and non-Africans alike have enthusiastically advocated the philosophy of ubuntu, it is not without its challenges.

Rhetoric and Reality

The first, and perhaps most significant, critique is that in many cases there is a huge gap between the espoused philosophy of ubuntu and the lived

experience of people in communities that purport to embrace it. The concept of ubuntu, by its very nature, tends to be most prevalent in societies facing substantial social, political, economic and environmental challenges. Such contexts, however, are often marked by large inequalities in the distribution of status, power and resources, which may be perceived as contradictory to the principles of ubuntu. Across much of Africa, there is a long history of corruption, coercion and collusion in politics, business and society, where those in senior positions benefit at the cost of those further down the hierarchy and the traditional concept of the monarch-chief continues to be influential at the local level. Whilst ubuntu has been put to good effect in challenging inequality and injustice during the Truth and Reconciliation process in South Africa, it arguably has done little to counteract endemic corruption and inequality elsewhere. Indeed, even in South Africa, it has been suggested that ubuntu, rather than challenging the status quo, may have been used by those in positions of political power to promote loyalty and respect and to suppress resistance to government-led reform. Whilst similar tensions exist in many societies, the challenge for those seeking to advocate a philosophy of ubuntu is how to reconcile such paradoxes without recourse to idealism, manipulation or denial.

The Limits of Interdependence

As a collectivist philosophy, ubuntu highlights the importance of interdependence and of people working together in pursuit of shared goals. A question remains, however, over how far this interdependence and collectivity can be extended. The concept of ubuntu developed at a time when African society was still largely organized around membership of tribal groups. Within this context, allegiance and loyalty were to fellow members of the tribe, and whilst there may well have been instances of collaboration and co-operation between groups, identity and identification were still largely based on ethnic and family relations. In an increasingly urbanized and globalized society, however, where do we draw the lines between communities and groups? Historically, part of the success of ubuntu was in articulating a framework for reciprocal responsibility whereby members of a particular group supported one another and, in so doing, increased the resilience and likely survival of the group. Where identification is extended more broadly and members of a particular group may self-categorize in different ways (e.g. as Africans, Nigerians, Igbo, Lagosians, etc.), the practical implications of ubuntu for the sharing of food, resources and so on become far more problematic. Historically, the power of ubuntu has been in forging stronger relationships between people in a particular

location; the prospect of its extension to other groups and cultures, whilst potentially attractive from an ideological perspective, may ultimately lead to its undoing as a practical solution to local problems.

The Connection Between People and the Environment

A further question raised by some authors is the extent to which ubuntu makes a false separation between people and the environment. Puleng Lenka Bula, for example, suggests that common conceptions of ubuntu (and the synonymous concept of *botho*) are anthropocentric in that they focus on human relations yet fail to recognize the connection with the physical and natural environment in which such interaction occurs. She calls for an extended notion that incorporates ecological and spiritual concerns, which, she argues, are essential elements of a framework for justice and ethics. By limiting our focus to human relations alone, it is suggested, we may inadvertently support harmful environmental practices and deny the spiritual concerns that guide many peoples' lives. By including these additional dimensions, however, we complicate matters, making it hard to achieve consensus or coherence of conclusions.

The Ontological and Epistemological Status of Knowledge

Finally, the concept of ubuntu raises fundamental questions about the nature and status of knowledge. As a relational philosophy that stresses the interdependence and intersubjectivity of knowledge and experience, it poses real challenges for the construction of an objective and enduring understanding. Whilst many advocates of ubuntu call for the sharing of 'indigenous knowledge', it is questionable whether any such knowledge base could be developed, and uncertain how it could be captured and communicated. All knowledge is culturally contingent, and the strongly constructivist nature of ubuntu would suggest that knowledge gained in one context may not be transferrable to other times and places. Furthermore, even if it were possible to develop a coherent body of knowledge, it is unclear whether this would lead to beneficial outcomes or simply an 'othering' of the context from whence it came as in some way 'different' and of questionable relevance elsewhere. Alternatively, ubuntu and related concepts may become appropriated by non-Africans and employed in ways that may diminish their clarity and potency.

Conclusion

This entry suggests that the African concept of ubuntu articulates a relational and compassionate world view that resonates with many of the principles of action research. It offers a means for expressing the interdependent and intersubjective dimensions of human experience and calls for an inclusive approach that embraces diversity, collaboration and the co-construction of knowledge. There are, however, some reservations about the extent to which the concept of ubuntu can be extended and employed in different contexts and the risks that this may pose in both ideological and practical terms.

V

VALIDITY

In research generally, validity pertains to the relationship between the research and the situation researched. Valid research adequately depicts what was researched. For example, in quantitative research, a valid measure is one that accurately measures what it purports to measure. A valid theory is one that describes well some relevant aspects of what has been researched. As described below, these relationships are not easily defined clearly in action research. A different conception of validity is required. On these grounds, some authors question the applicability of the term *validity* to action research and recommend substituting different concepts. Others continue to use the term with modification.

This entry briefly describes the approaches to using or avoiding the concept of validity. Some of the sub-varieties of validity are identified. The entry concludes with a brief discussion of the main threats to validity in action research and some of the strategies for addressing those threats.

Applicability of Validity to Action Research

The concept of validity was developed in traditional quantitative research, where it fits well. A well-conducted physical experiment when it is replicated is likely to give the same results as before. When it does, the accuracy—the validity—of the findings can be accepted with confidence. In contrast, situations involving human actors in interaction are characterized by greater uncertainty and unpredictability. Action research studies such situations, which may be described technically as ‘complex systems’. Very often, these systems can behave very differently than the way simple physical systems behave. As a consequence, different repetitions of an action research study are unlikely to yield identical results except at high levels of abstraction, and not always then.

In action research, attitudes to the use of validity as a concept subdivide researchers into two camps. Influenced by the US qualitative research literature, there are those who favour the replacement of validity by other concepts. Others use the term, while advocating its modification to suit the requirements of action research. In some action research literature, the term *quality* is used rather than validity, while other authors such as Hilary Bradbury and Peter Reason use the two terms more or less interchangeably. Similarly, some treat validity and trustworthiness as interchangeable terms.

Yvonna Lincoln has been an influential advocate of the view that qualitative research should develop its own criteria for evaluating research. Her views have been influential in action research too. Initially, her criteria took the form of labels for concepts that were analogous to their traditional counterparts. Rigour was translated to trustworthiness. Internal validity became credibility, and external validity or generalizability became transferability (see below). Lincoln has since developed other terms that are not translations of traditional concepts from quantitative research. However, her earlier concepts still have wide currency, again also with some action researchers. For many who take this view, there is a concern that, evaluated against traditional criteria for validity, those who don’t sufficiently understand non-traditional research may find action research and qualitative research wanting.

Janice Morse is an example of those who hold a contrary view. Motivated by a wish for qualitative research to be accepted as a legitimate form of research, she argues that it is to the advantage of qualitative researchers that they are accepted as part of the wider research community. To this end, quantitative concepts of validity can be translated to fit qualitative research. Part of this argument is that qualitative research (and by implication action research) can be performed to sufficiently high standards that its quality can be defended against those who question it. Qualitative research, quantitative research and action research can then be treated as

complementary research approaches suited to different research situations and purposes.

Influences on Definitions of Validity

Underpinning these differences, the form and even the relevance of the concept of validity depend both on the style of the research and on the philosophy of the researcher. Traditional quantitative research is able to adopt the positivist stance that the world is essentially as we perceive it, either directly or through the use of our instruments. Where situations can be understood by first understanding their components, positivist research methods work well. Conventional definitions of validity are then appropriate. More complex situations lack this predictability. They require different approaches and different ways of conceptualizing them.

The opposition to positivist views and traditional criteria is most evident from those who hold a strong constructivist position. Such a position asserts that all knowledge, including scientific knowledge, is necessarily a social construction. On this view, reality is unknowable, and 'truth' becomes an undefined term. There are then no safe grounds on which two pieces of knowledge can be compared for accuracy. As Allan Feldman has pointed out, such a position offers no possibility of evaluating competing claims. There are other, less extreme constructivist positions in which competing claims can to some extent be judged. Morse has also posited that the constructivist approach may have the undesirable effect of shifting attention to validity from the design phase of research (see later) to what happens after the research is complete.

Two other philosophies appear to be increasing in currency. Critical realism adopts a position incorporating some aspects of both positivism and constructivism. Like positivism, it is ontologically realist in assuming the existence of an actual world. Like constructivism, it is epistemologically fallibilist in its treatment of knowledge as tentative and only partially accessible. It also offers a layered and systemic view of reality in which intangibles such as human attitudes have material outcomes. Knowledge can be pursued and used without demanding certainty.

Pragmatism has a long history in action research. It is experiencing a partial resurgence after being sidelined for a time by constructivism. It weighs relevance as more important than rigour, thus appealing to practitioners who are often satisfied with the practical outcomes from their research. It seeks evidence for research validity in the outcomes of the research. Jacqueline Fendt and Renata Kaminska-Labbé have summarized the current views, especially as they apply to the gap between theory and practice.

Given this confused background, it is not surprising that there is no precise and agreed-on definition of validity in action research. Anything more than a broad characterization may be ambitious. Roughly speaking, validity may be described as the extent of fit between some research element (e.g. data, explanation or proposed actions) and some phenomenon that the research element refers to. An attempt at a more precise definition must deal with two issues. First, as mentioned, the easy replicability of physical experiments is seldom available in field research, where each research situation is more or less unique. Second, and related, the complexity of field situations seldom allows a full description of that situation and also increases unpredictability.

Varieties of Validity

In traditional quantitative research, there is general agreement on several subcategories of validity. At the most general level, a distinction is made between internal validity and external validity. Internal validity refers to the validity of inferred relationships (typically, causal relationships) between the variables that have been studied in a particular piece of research. For example, a force applied to an object (in the absence of other forces) causes the object to move predictably. External validity is equivalent to generalizability. It applies when the findings of a particular study can be extended to apply to other studies. A given force applied to an object of given mass produces equivalent movement in other equivalent situations.

There are many other sub-varieties of validity in quantitative research. Their descriptions and labels are widely accepted by quantitative researchers. They are not further discussed here. In action research, the situation is again less clear. In some formulations, validity is sought in the research report rather than in the research itself. In others, as Morse has pointed out, validity is something that is achieved after the research is done rather than (as Morse prefers) being part of the conduct of the research. Participant validation is an example, where research findings are distributed to the participants for comment.

Writing about qualitative research from a constructivist perspective, Steinar Kvale proposes three varieties of validity that do apply to the actual conduct of the research. They are craftsmanship, communicative validity and pragmatic validity. All can be applied to action research whether or not a constructivist philosophy is adopted. They remain relevant when a pragmatic or critical realist stance is taken. Craftsmanship, as the word implies, is displayed in the care and mindfulness of the researcher as the research is carried out. Communicative validity arises from the way in which

interactions between researchers and participants occur and is akin to Anderson's dialogic validity, discussed immediately below. Research exhibits pragmatic validity when it yields favourable outcomes for the research participants. It resembles Anderson's democratic validity.

In some areas of action research, the formulations of Gary Anderson and his colleagues have achieved some acceptance. Kathryn Herr and Anderson postulate five varieties of validity, specifically applying to action research and evaluated by the outcomes achieved by the research. Catalytic validity applies to research that produces some transformation in the participants. It can be evaluated by assessing the learning that researchers and participants achieve. Research has outcome validity to the extent that it leads to action that achieves the research purposes and outcomes. Research with process validity has used appropriate means to pursue the outcomes and is evaluated by the knowledge it produces. Dialogic validity refers to discussion between stakeholders that is sufficiently critical and deep, also yielding new knowledge. Democratic validity is achieved when research involves stakeholders collaboratively in ways that produce outcomes that are locally relevant.

Overcoming Threats to Validity

Implicit in the validity criteria described above are certain threats to validity, and certain ways of reducing or eliminating those threats. As validity depends upon quality information, strategies for improving reliability can also improve validity—see the entry on reliability in this encyclopedia. Validity and its threats can also be categorized in terms of the aspect of action research where they are found and managed. Action research can be described as participatory, pursuing both action and understanding, and iterative. A few examples of each will suffice.

Consider the nature and extent of participation. Questions such as the following can be raised: Are the appropriate participants involved? Are they engaged in such a way that they find it easy to tell the truth as they see it? Is there a climate in the study and a style of interaction that allow differences to be resolved constructively, leading to deeper understanding?

Or consider action and understanding. How easily does the understanding inform the actions? Are the actions chosen on the basis of an understanding of the situation that is to be changed? Are the people who identify the actions the same people who will carry them out? Were the actions agreed on in such a way that people are motivated to carry them out as planned?

Finally, the iteration within the action research spiral allows the knowledge and action to be built up

cumulatively. Through trial and error, if necessary, both action and knowledge can be pursued until achieved.

VIVENCIA

The concept of *vivencia* is a crucial, and sometimes disputed, component of action research. *Vivencia* is often translated into English as 'lived or life experience'. It is more than this. *Vivencia* is the essence of treating people as actors in their own lives and recognizing that what they bring to the table is integral to all research for social change. *Vivencia* acknowledges what people know and believe and uses their present reality as a starting point for all work. It then builds upon the existing knowledge as expressed by the most affected to continue to study for the purpose of engaging in social transformation.

Further, vivencia recognizes that what happens between people—the relationship that exists—is critical to an understanding of their world and their reality and equally critical to making lasting change to that reality. This means that the research process is demystified so that all are able to comprehend and actively participate as equals in the process. It permits research to be understood as a political process of rediscovering and re-creating personal and social realities, as well as producing new or recovered knowledge, allowing oppressed people to generate an assertion of their knowledge. Vivencia grounds all forms of action research in the belief that all persons have intellectual capabilities and the capacity to generate knowledge.

Using vivencia as a point of departure, Orlando Fals Borda suggested that the purpose of research is not just to build knowledge or test interventions but to take action towards social justice. This is referred to as the democratization of knowledge and has its roots in the vivencia of real people. Fals Borda further pointed out that an intricate part of this vivencia has to do with the relationships that are an integral part of the research process. In most research methodologies, there are hierarchical relationships based on submission. In action research, the relationships are of mutuality and partnership. Therefore, vivencia is a practice of participatory democracy that demonstrates the value of a commitment to full democratization in both content and method. This process is often feared by those with power. Fals Borda noted that the practice of reflecting upon the vivencia of the people and pursuing an agenda based upon that reflection leads to a process whereby grass-roots movements become empowered and those in power become alarmed by that empowerment.

In action research, vivencia is expressed when a group of people collectively enter into a living process, examining their reality by asking penetrating questions, mulling over assumptions related to their everyday problems and circumstances, deliberating alternatives for change and taking meaningful actions. The group has ownership over what questions are pursued based on its members' vivencia. Vivencia talks about how important the process of seeing and learning with both the brain and the heart is in creating a new society that is egalitarian. This means that those persons who previously were the focus of study, or the objects of study, are now the experts in their own lives and actively engaged in the research process. As such, Fals Borda recognizes that action researchers can be considered members of social change movements based upon a critical understanding of vivencia. These movements are engaged in practice—both research and action—that recognizes that those most affected by the injustices in society know more about their own situations and therefore need to be in the forefront of making change happen.

Rather than having knowledge produced about them, they, too, are engaged in the production of knowledge.

In this way, it is the vivencia of those most affected in society—the oppressed, exploited, vulnerable—that is prioritized over the vivencia of the privileged, including members of the academy. Vivencia calls on researchers to use methods and strategies that are not typically used in the academy—to partner with grass-roots people as the experts in their own lives and to express their knowledge through creative means. It asks researchers to critically analyze the reflexive relationship between 'us' and 'them', giving preference to those who are typically considered 'them'.

Vivencia, then, necessarily includes the process of conscientization—stimulation of self-reflected critical awareness on the part of oppressed people of their social reality and of their ability to transform it by their conscious action. This is the essence of vivencia, and of any research that aims to work diligently against social and economic injustice.

VOICE

Voice is a versatile term, used in research to describe the ability, mode and/or right of individuals or groups

to make their ideas, opinions, emotions, perspectives and needs known to others. Similarly, *to voice* is to make such an expression, while *to give voice to* is to allow or support this expression. In the domain of action research, voice becomes more than just an innate way to express oneself; it is also a way to participate and engage in conversations around social justice and change.

The first voice to consider is that of the researcher, whose feelings, experiences, interests and positionalities cannot be divorced from the topic of study and, indeed, are often the basis for an inquiry. Most action research involves a measure of relationship and trust wherein both the researcher and those researched must allow each other into their lives in order to explore an issue together fully. The researcher must be aware of his or her own voice in order to remain transparent in advocating for the voices of others.

Voice can be a profound source of empowerment for all involved, but particularly for those parties whose voices have traditionally been marginalized, ignored or completely silenced. Voice is a necessary aspect of agency, or the capacity to make choices and act for oneself, which for many has also been compromised. Action researchers who wish to validate the experiences and ‘ways of knowing’ of the participants in an inquiry are first tasked with uncovering the true voices of those participants, which are all too often influenced by undercurrents of power and privilege, cultural barriers and similar inhibitors. Moreover, they must know where to find those voices.

Voice comes in many forms and serves various purposes, from personal to collective, private to activist. It is embodied not only in words but also in silence, abstinence, action, demonstration, appearance, artistic expression and so on. It is not limited to traditional avenues of speech and writing, but it can also be found through narratives and storytelling, Photovoice (the use of photography to document one’s perspectives), inclusive debate and dialogue and anywhere else individuals or groups have the opportunity to express themselves by whatever means necessary and without limitation or judgement. There are voices of all colours, shapes and sizes, diverse in race, class, gender, age and ability; and there are voices that require advocacy, such as those of the dependent and/or incapacitated or the ‘voices’ of the natural environment, non-human beings and other entities or causes that need an interpreter. Finally, not all voices and expressions of voice can be objectively separated from one another, as they inherently coexist in an ever-changing, interconnected web of stimuli and experience, of history and possibility.

The action researcher must consider all these facets of voice within the scope of a study. As a starting point, this entry will further explore issues of voice with

regard to power dynamics, authenticity and ethics, and their accompanying implications for action research.

Power Dynamics and Voice

The main questions one must ask in regard to voice are as follows: Whose voices are being heard? Who is listening? Why? In research, a voice is representative of something particularly intriguing to the researcher and is likely characterized by some sort of ‘otherness’, or previously misunderstood or missing perspective. Because power dynamics affect whether voices are heard and how they are portrayed or perceived, they also determine the hierarchy of knowledge within communities, institutions and society. Those voices with the most power get heard and, additionally, have the capacity to control how other voices are represented, which can often be worse than silencing these voices and typically serve to reinforce unequal power structures. For many, fear of reprimand or retaliation has stifled their voices, so that their perspectives are only partly knowable or, worse, completely inaccessible.

Power also affects whose opinions and ideas matter and whose do not, such as when weight is given to the words of academics and other ‘experts’ but not to those of the population experiencing a subject firsthand. Action researchers, conversely, aim to use their scholarly influence to give voice back to the people in their research, recognizing that there are multiple truths, multiple ways of knowing beyond their own and therefore seeking research conditions that foster visibility and safety for the expression of these alternative voices. Participatory Action Research, for example, includes community-based ‘co-researchers’ in a study, wherein the subject population of an inquiry is given power to co-create the questions, methods, data collection, analysis and action of that inquiry. Overall, fair representation and breaking the barriers of hierarchical influence are vital to overcoming the adverse effects of power dynamics on voice. Research participants must be empowered to aspire, to be leaders, and to effect institutional, societal and political change for themselves.

Authenticity of Voice

Once a voice is allowed to surface, it becomes important to ensure the authenticity of that voice for research purposes. Culture, education, media, politics and so on are highly influential and can either support or alter one’s authentic voice. This is not to say that such a voice can only exist in a vacuum—individuals are surely shaped by their experiences—but that an authentic voice should be a voice that truly speaks for itself. For instance, the unadulterated voices of

youth are sometimes difficult to uncover beneath the ideas and attitudes instilled in, and often expected of them, by parents, peers and the culture in which they were raised. Likewise, personal challenges and self-perceptions can change the way one sees the world and one's place in it. Hardship and marginalization are disempowering and can dilute a person's ability to speak in his or her own interest. Here again, authenticity becomes entwined with power and privilege, where those voices with power are buoyed up by confidence and those without are often shaken and unsure, internalizing structural failings as their own. Outwardly conveying one's intuitive voice can feel dangerous or wrong in these instances, so it is necessary for researchers to establish a safe and trusting space for exploring true feelings and ideas.

Other ways the authenticity of voice can be derailed are through misinterpretation and devaluation. It is all too common for displays of voice that do not align with 'mainstream' societal norms to be misunderstood and/or quickly dismissed. Perhaps some might automatically interpret a teen's loud music and non-conforming dress as rebelliousness. From that teen's point of view, these may very well be to protest, defy or offend, or they may only be self-expression, voicing his or her tastes and ideas. This is why it is important to seek first-hand insight into the pertinent voices of a topic. A person or group can tell their own story if given the opportunity, so it is in the researcher's best interest to seek not only participants' endorsement but their direct input when making analyses.

One must also acknowledge that results may not be true for larger populations—may not be generalizable—but that does not make them any less authentic for the subject individual or group. This illuminates another notable barrier to authenticity, which is the common error of assuming that a voice is always representative—as in 'Because this is the voice of a homosexual Latino man, working in this type of job and living under these conditions, this must be the voice of any and all such homosexual Latino men'. While it can be valid that these men would have a lot in common, they are still individuals, and their life experiences and how those translate into voice are unique. The goal of action research is not to identify a singular voice to speak on behalf of a universal need but instead to identify particular voices, which when added to other voices can be a force for change locally, and eventually globally.

Issues of Ethics Around Voice

It is often difficult in research to uncover voices that are authentic, unhindered by power structures and, most important, willing to tell their stories to outsiders.

One of the greatest challenges action researchers face, despite their sincere desire to help historically disenfranchised people, is that based on past experiences these groups often do not trust the intentions or actions of researchers. Traditional methods have tended to exclude participants not only from the meaning making of a study but also from the end results and benefits. In the worst cases, people's voices may have been used to cover up others' manipulative practices, or they may have been decontextualized to support someone else's agenda. Deserving, gaining and keeping the confidence of one's community contributors are primary ethical concerns for action researchers. Further matters to consider include creating the conditions for true collaboration, protection of participants and acting on and disseminating the knowledge gained.

As previously stated, all researchers bring their own voices to the table, and transparency builds trust. Participants must see clearly not only the goals and methods of the research but also the personal connections and aims of the researcher, opening dialogue on how the inquiry can support everyone's ideals and interests. Ethical relationships in action research must go beyond the requisite, traditional protocols. The more researchers work on equal ground with community members, the easier it becomes for everyone to contribute their voices openly. Participatory research methods are the easiest way to ensure that all voices receive equal opportunity to affect the results of a study. Under ideal circumstances, there are no researchers and the researched, only co-researchers and their topic of inquiry. The most accurate and rigorous results come from intensive collaboration between all voices within a research community.

In some research, participants take a great risk in expressing their voices. Extreme care must be exercised when evaluating the possible repercussions of such a study. Practitioner action researchers, for example, often face pressures from within their organizations that may threaten their friendships, positions or livelihoods if they voice unfavourable information about the organization or its other members. It is therefore imperative that researchers weigh the outcomes of their findings and how they plan to publicize them with the amount of risk involved for everyone who could be affected, and take whatever steps necessary to ensure that no one's well-being is jeopardized unwillingly.

A final distinction between the ethics of action research and traditional methods is, as implied, the action of the work. The goal of finding, listening to and evaluating voices is not only to generate an academic product or to contribute to some abstract knowledge base on a subject but also to deliver a measurable

benefit for the participants. Action researchers may be under the same pressures to publish and circulate their work within academia as other researchers, but at the same time they will want to have learned something new and made a difference in the lives of those they study. To do this, they endeavour to share results and actions with their partnering individuals and communities, and it is not uncommon for final reports to come directly from the participants, through public speaking, writing, the arts and other forms of open expression and dissemination.

As the only life forms on earth capable of using sophisticated language, we human beings appear evolutionarily inclined to make our thoughts known through the use of a literal voice, and our complex intelligence enables us to communicate in a variety of unspoken ways as well as to advocate for others. These biological developments demonstrate that voice may be one of the most fundamental of all human abilities, important to our survival, well-being and overall progress. Action research aims to support this capacity for voice through participatory and inclusive inquiry into issues that affect human and environmental flourishing on both the individual and the universal level.

VOLUNTARY SECTOR

The voluntary sector can be defined as a sector comprising a group of organizations or collectives of individuals working for the betterment of society and for the common public good. It serves as an important link between the citizens and the government. The social change initiatives of the sector would encompass initiatives as diverse as welfare services for the poor and excluded, strengthening the capacities of the marginalized, undertaking research interventions and influencing policies for social change.

The roots of participatory research and Participatory Action Research can be found in the early initiatives of the voluntary sector. Early proponents of the sector recognized that critical reflections of their own realities by the marginalized have the potential to ensure collective action by them to enhance their life conditions and address injustices, leading to a dynamic cycle of critical reflection and action. The action research philosophy thus forms a fundamental component of a large number of transformational initiatives facilitated by the voluntary sector.

This entry provides an understanding of the voluntary sector, traces the history of the sector with the help of an example from India, explores the role of the sector in addressing the issues of socio-economic development of the marginalized and concludes by tracing the challenges faced by the sector.

Understanding the Voluntary Sector

The term *voluntary* is derived from the fact that the early efforts of the voluntary sector had their genesis in charity, philanthropy and relief activities, driven by the sector’s belief in selfless service to the society.

In the current scenario, the nomenclature for the voluntary sector includes terms like *non-government organizations* (NGOs), *non-profit organizations* or *not-for-profit organizations* (NPOs), *civil society organizations* (CSOs) or *the third sector*. These terms are generally used when these institutions are incorporated under the local laws of registration. Along with these formal entities, the voluntary sector also includes informal, unregistered grouping of people coming together for a common cause, like community-based organizations, traditional groups, social movements and social activists. It also includes networks of the formal and informal groups, as well as professional and membership associations.

One way to understand the voluntary sector is from the type of functions formed by the different organizations covered under its ambit. An important cluster of organizations within the voluntary sector are those

organizations which primarily provide basic services to the poor and marginalized, in areas like education, health or sanitation. The second group of organizations in the sector includes those who are involved in awareness generation and organizing work with vulnerable groups, which includes providing information to the marginalized about their entitlements under the law or the provisions under the various government-sponsored schemes. The third category includes groups which are involved in research and advocacy endeavours. They provide feedback to policymakers and negotiate with and on behalf of the excluded. There are also groups which define themselves as support institutions, providing either financial or technical support to the above groups so that they can undertake their interventions in an effective manner.

The varied interventions and innovations in the voluntary sector have been grounded in and facilitated by action research and its related approaches of Participatory Action Research and participatory research. Participatory approaches are used at different stages of the development programmes to mobilize and sensitize the community, advocate for the rights of the marginalized and facilitate action research interventions by the constituents of the voluntary sector.

History of the Voluntary Sector: Case of India

The evolution of the voluntary sector has followed different trajectories in different countries. Using India as an example, this entry attempts to explain the evolution process of this sector.

Like any other country of the world, India also has a long tradition of voluntarism, philanthropy and charity. The primary role of the state has always been providing security and basic infrastructure to its citizens. The state also provided welfare activities like health, education and social security to its citizens. The well-off segments of the community also provided basic services like free health or education to the poor, and institutions were also created to support the efforts of the government to provide a better quality of life to the poor.

The first attempt to provide a regulatory structure for volunteerism in India came with the Societies Registration Act of 1860. This was a period when various socio-educational movements were taking shape and a need for institutionalization of these initiatives was felt. A critique of this act has always been that it was an attempt by the British administrators to provide a regulatory structure to the sociopolitical movement in India to track such groupings. Many outstanding voluntary organizations were formed in India from 1860 to 1947 that made remarkable contributions to the fields of education, health and socio-economic reform.

These included religious and faith-based groups, temples, educational institutions and philanthropists who facilitated the delivery of services in remote locations.

The second phase of growth came after India gained independence in 1947. The freedom movement of India was led by Mahatma Gandhi. After 1947, he gave a call to the people to come forward as social activists, and many organizations were formed by the freedom fighters who believed in the principles of Mahatma Gandhi. Such organizations were commonly known as 'Gandhian organizations'. The institutions formed under this movement were primarily engaged in socio-economic development of the marginalized. They believed in the philosophy of simplicity, non-violence and universal brotherhood.

The third phase of development of voluntary organizations came after the movement led by Jay Prakash Narain against the internal emergency declared by Prime Minister Indira Gandhi in 1975. Thousands of youth leaders participated in the mass movement against the autocratic regime in the mid-1970s. After the movement, they abandoned their professions and started working for the upliftment of the marginalized masses. This was the period when not only numerous innovations took place in the sector but also many critical and reflective documents were prepared on development discourse.

The late 1970s and early 1980s marked the beginning of more professional voluntary action in India. Professionally trained volunteers began to enter the voluntary sector and undertook various developmental initiatives. This led to numerous innovations in service delivery areas such as health, education and sanitation and in various methodologies for training, evaluation and impact assessment. These innovations of the sector were replicated and scaled up by the government.

The 1980s and 1990s saw growing recognition, support and funding by the government and international donor agencies, and the increased emphasis towards people's participation in various development projects contributed to a more rapidly growing voluntary sector. However, due to the old laws, many types of institutions which were not necessarily voluntary organizations were registered in the non-profit category. These included sports clubs, resident welfare associations and government-sponsored institutions, amongst others. In recent years, there has been an upsurge in corporate social responsibility initiatives of the private sector, with many new private foundations being formed and working in the areas of socio-economic development, with a greater focus on service delivery initiatives.

The voluntarism in India, thus, has undergone changes, and in the current context the voluntary sector has an important identity as the third sector, the other two being the state and the market. In other countries

also, the voluntary sector has evolved through the years, following a unique trajectory based on the context of that country.

Strengthening Citizens' Participation

The voluntary sector has made significant contributions to facilitate social and economic development in the countries, ensure effective governance and deepen democratic processes.

Internationally, a very important role played by the voluntary sector and the agencies associated with it is enhancing the participation of citizens and the community in development and governance interventions. The voluntary sector aims to stimulate the active participation of citizens in matters that concern them and their community, using action research and Participatory Action Research approaches. The facilitation of collective inquiry, knowledge production and utilization of the knowledge by the citizens and communities is a very important role and contribution of the voluntary sector. The use of different participatory development and social accountability approaches, building on the philosophy of Participatory Action Research, like participatory planning, participatory monitoring and evaluation and social audits are important contributions of this sector.

The voluntary sector has historically played a very responsible and constructive role in public service delivery. Innovations in incorporating Participatory Action Research interventions in service delivery interventions by the voluntary sector have helped in demonstrating an empowering and sustainable model of development work at the grass roots.

There is a marked increase in the participation of the voluntary sector in policy processes in different countries. Voluntary agencies are increasingly playing a very important role in influencing policymaking and policy implementation on diverse national and global issues. The generation of knowledge and the use of this knowledge to influence policy, both components of action research philosophy, are also important contributions of the voluntary sector.

The voluntary sector also has a significant role in balancing the forces of the state and the market, in ensuring that they are both accountable to the citizens and that the needs and aspirations of the citizens, especially of the marginalized, are met.

Challenges

The sector faces a spectrum of challenges from both within and outside its remit, in performing its significant role in society. Some of the key challenges in the current context include the following.

The changing global economic scenario has implications for access to resources for the activities for the voluntary sector, especially for the work of the organized section of the sector, like the NGOs and CSOs. A number of countries of the Global South are facing a reduction in their official development assistance, thus affecting the work of the voluntary sector, especially on interventions dealing with awareness generation and policy influence work. In the countries of the Global North, the economic recession has also affected government support for voluntary or civil society action, within their own countries as well as externally, with some functions of the sector being negatively affected more than the others.

With the reduction in financial aid, the organized section of the voluntary sector also face increasing pressure to ensure transparency in their dealings, to build in effective internal governance mechanisms and to demonstrate concrete changes in the lives of the community. This is in keeping with the demand for their upward accountability to the resource providers; downward accountability to the recipients of their services, which in most cases includes the poor, deprived communities, and horizontal accountability to their peers in the sector.

Ensuring effective inter-agency collaboration between the voluntary sector or the third sector, the state and the market is another challenge. Each of the three sectors has a unique character, and how they interact with each other varies across different cultures, regions and countries of the world. The collaboration among these three sectors thus can be quite complex and sometimes antagonistic. For example, the stringent laws and regulations of the state are adversely affecting the functioning and sustainability of the sector across many countries of the Global North and South. Further, the growing role of the private sector in social development issues, in the form of their corporate social responsibility intervention, also has implications for the shrinking space and positioning of the voluntary sector.

WHOLE-SYSTEMS ACTION RESEARCH

See Systemic Action Research

WHYTE, WILLIAM FOOTE

For many students and scholars in North America, William Foote Whyte's work represented the first exposure to the idea that people learning and working together to improve things could succeed much more readily than individuals working in isolation. For many, too, who had missed the practical reform work of Paulo Freire in Brazil and Myles Horton in the southern USA, Whyte's writings introduced us to the potential in empowering problem holders to solve their own problems. The researcher in such a situation takes on the role of co-learner rather than know-it-all expert. The researcher helps problem holders organize and find the resources to create positive social change but does not impose his or her ideas for change. Indeed, Whyte persisted until the end of his life in adding the word *participatory* to "action research" to emphasize the significance of engaging those who might otherwise be seen as 'subjects' in the research.

Whyte was born June 27, 1914, in Springfield, Massachusetts. He grew up in the Bronx, Caldwell, New Jersey, and in Bronxville, New York. He graduated from Swarthmore College in Pennsylvania in 1936, having majored in economics. Following this, he went on to 4 years at Harvard University as a member of the Society of Fellows, followed by 3 years at the University of Chicago, where he received a Ph.D. in sociology with a minor in social anthropology. Whyte began his teaching career at the University of Oklahoma. In

1943, he contracted polio and spent a year at the Warm Springs Foundation in Georgia, where he learned to walk with a cane. From that point on, Whyte conducted all of his fieldwork with the aid of crutches or a cane. From 1944 to 1948, he taught at the University of Chicago and then moved to Ithaca, New York, where he joined the faculty of the New York State School of Industrial and Labor Relations at Cornell University. When he retired as an active faculty member, he co-founded Programs for Employment and Workplace Systems to promote the engagement of faculty in participatory action with union leaders and managers. He died in Ithaca on 16 July 2000.

In his autobiography, *Participant Observer*, Whyte recounts a lifetime of research projects that illustrate the role of the participatory action researcher. A clear example of why participation is critical can be seen in his 1950s work with poor farmers in Latin America, as part of a Cornell University rural development project. He went there to study the organizational and cultural issues in the introduction of new farming technology. It turned out that the local farmers' rational practice of growing corn with beans meant that growing a new, high-yielding variety of corn would not work. Local knowledge was needed for the successful introduction of technology. Inclusion of peasant farmers in the planning of agricultural improvement would lead to far better results.

In his earliest study, published in 1943 as *Street Corner Society*, Whyte's approach was unconventional because he engaged as a participant in the social world of the people he was studying. When Whyte reported to one of the Boston gang members he was studying that he 'just want[ed] to understand these things as best I [he] can and write them up,' he was challenged to believe that in writing about the conditions of poverty and lack of work the gang members experienced, he might be able to change things. He came to understand that he was working *with* the group of young men he was studying.

There are countless stories among Whyte's students and colleagues of his broad reach into fields of study

beyond his own: While he began with organizational behaviour with the gangs in Boston, this expanded to human relations, the human response to technical change, union-management cooperation and worker ownership, to name a few. What is common in this activity is the search for what people can accomplish together.

Stepping back, it is easy to see that Whyte's practice showed a way for action researchers who were attracted to the philosophy of inclusion and collaboration but were uncertain about how to combine this with what was understood as research. From the beginning, Whyte exhibited habits of mind that lasted a lifetime. These habits of mind describe a framework for action research: rigour, a commitment to joint learning, inclusion and a determined focus on social reform as an outcome for research.

Whyte's rigour as a researcher showed up early in his life. His own account of the research for *Street Corner Society* shows him, involvement notwithstanding, retreating to the men's room in a bar to record notes of conversations he'd just witnessed. The action researcher is not a sloppy researcher. Whyte kept records meticulously throughout his life, a habit that was confirmed when he revealed near the age of 80 that the source documents for his autobiography included letters he'd written to his parents while at college. And he was rigorous in his inquiry; he kept track of his own mistakes, but more important, he was critical in his feedback to the institutions he studied. The latter included his own employer, the School of Industrial and Labor Relations at Cornell University, and the Cooperatives at Mondragón, Spain.

Whyte's assumption that by including others we learn more applied not only to the participants in his studies but also to colleagues. Stories are told by many former students and colleagues about how he liked to gather people together to think about projects. This is how Davydd Greenwood, a Cornell anthropologist, ended up in Mondragón; it was responsible for the practice of communal reflection on projects in Cornell's PEWS (Programs for Employment and Workplace Systems), which Whyte founded. At a distance now, one can see now the connection between this 'habit of mind' and the post-Whyte development of collaborative inquiry by Peter Reason and others at Bath University and Lyle Yorks at Teachers College, Columbia. This way of learning deepens the capacity of action research.

As to social reform, that was always Whyte's thought, though it was exercised in ways professional reformers might not recognize. By raising awareness in early 1940s Boston, by writing about employee ownership, by listening to Peruvian peasant farmers, by sticking his neck out in the late 1960s period of university

strife to support a local alternative school and by founding PEWS, an active labour-management programme in the School of Industrial and Labor Relations Extension Division—quite in the face of academic disdain—Whyte proved to be an active reformer.

One might say that Whyte habitually supported people—including himself—acting outside of accepted and expected patterns. This brings us back to the core qualities of inquiry and reflection that characterize action research. In his work and in his writings, Whyte offers a model of these practices as a way of life.

At the time of his death, the *New York Times* wrote that Whyte had written '20 influential books'. That didn't include countless articles and other books. For an introduction to his work, two extremely influential books, *Street Corner Society*, referred to above, and *Learning From the Field* (1984), a guide for social science researchers that, if read carefully, instils the values of action research, can be recommended. For an overview of Whyte's work and life, and to decide what else you might like to read, *Participant Observer* (1994) can be recommended. Finally, a perhaps forgotten volume he wrote with colleagues and students, *Worker Participation and Ownership* (1983), is worth tracking down. The subtitle of this volume is *Cooperative Strategies for Strengthening Local Economies*, a topic as relevant today in the second decade of the century as it was then and a fine example of Whyte at work collaboratively with others to do research that will make a difference.

WITTGENSTEIN, LUDWIG

Ludwig Wittgenstein (1889–1951) was an Austrian philosopher who had a major influence on logical positivism and analytic philosophy. This entry focuses on

how his thought is influential in action research in that, in his remarks, he highlights how actions are shaped and rendered meaningful only by occurring within particular surroundings; lacking a context, they are literally senseless.

In action research, where inquiries are conducted from within one or other particular organization, or a particular practice within it, with the hope of improving that organization or the practices within it in some way, inquiries are thus practice driven rather than theory driven; similarly, words come to make sense by being used within a specific situation rather than within a theoretical framework. Thus, for Wittgenstein and for researchers with people's activities as their central focus, 'the words you utter or what you think as you utter them are not what matters, so much as the difference they make at various points in your life. Practice gives words their significance'. So although in the fields of management and organization studies terms such as *leadership*, *expertise*, *organization*, *system*, *strategy*, *innovation*, *motivation* and so on are used, and actionable knowledge is sought by practitioners in the hope of understanding how to implement appropriate causal processes to bring about such things, as Wittgenstein sees it, there are no such things in existence for these words to refer to.

Indeed, these words in fact refer to certain characteristics that are observed in people's activities only after they have been performed. Thus, in Wittgenstein's terms, theory-driven, scientific forms of inquiry arrive on the scene too late and look in the wrong direction with the wrong aim in mind—too late because scientists act as if the basic elements of their analyses are already there in existence as fixed, determinate and nameable entities; in the wrong direction because they look backwards towards already existing actualities rather than forward towards possibilities; and with the wrong aim in mind because they seek a static picture or theoretical representation of a phenomenon rather than a living sense, or sensing, of it as an active agency at work in shaping lives now, in the actual place and actual time of their enactment.

This is what makes Wittgenstein's kind of investigations so special: They are concerned with ontological rather than with epistemological issues, with reflexive rather than reflective investigations, with changing us in ourselves and not just our knowledge. Given researchers' training as rational thinkers and scientific investigators, they are inclined to think of all the difficulties they face as problems that can be solved by the application of a science-like methodology. But as he sees it, besides such difficulties of the intellect, they can also face a difficulty of the will, a difficulty that manifests itself in each new situation when they encounter what, spontaneously, they want to see. Relational or

orientational difficulties such as these cannot be overcome by the application of any current theory-driven methods of inquiry. They are difficulties to do with the embodied expectations and anticipations with which researchers go out to meet the detailed features of their surroundings, and thus to find their way about and to go on within them without (mis)leading themselves into taking inappropriate next steps. Thus, the difficulties they need to overcome involve a working on the way they see things (and what they expect of them).

Thus, if researchers were to liken what is involved in arriving at theory-based, scientific understandings to the learning of a second language, they will come to know that some of the hidden processes behind the appearances already well known to them are really other than what they appear to be; Wittgenstein's concerns are with their elaborating their first language learning. That is, he is concerned not with their reflective abilities but with their sensing, with their ability to learn to pick out distinctive features within an otherwise fluid, indeterminate circumstance and their ability to draw attention to these features, linguistically, to others. The task is not translation but language learning.

Thus, straightaway, Wittgenstein engages researchers in a set of practices very different from those they normally undertake when faced with a bewildering or difficult situation. Instead of beginning with an analysis of it, into its supposed elementary parts, he asks researchers to undertake a set of imaginative practices or different ways of seeing things or other methodical ways of thinking—all drawing on their already lived experiences—aimed specifically at both overcoming their intellectual ways of relating or orienting themselves to their surroundings and coming to know their way about within the unique concrete situations that bewilder them. And as they explore the unique qualities of their initial bewilderments, researchers can come to feel so much at home within their bewilderments, he suggests, that they can come to see previously unnoticed possibilities for going on; thus, the bewilderments guide their next steps in terms of the degree to which they satisfy the sensed disquiets they initially aroused within the researchers.

In all of this, it is researchers' use of words that is crucial. For it is how a word is used in relation to its particular surroundings that gives it its meaning—its practical meaning. As a reminder, Wittgenstein says, 'I shall also call the whole, consisting of language and the actions into which it is woven, the "language-game"'—where the idea of a game is meant to remind us that things occurring within a game have a quite different meaning or use from those occurring outside it. He thus describes the turn, or the change in attitude he intends here, as being of the following kind. When philosophers

use a word like *knowledge*, *being*, *object*, or *I* and try to grasp the essence of the thing, one must always ask oneself, 'Is the word ever actually used in this way in the language game which is its original home?' What we do is to bring words back from their metaphysical to their everyday use. For, as Wittgenstein sees it, when used in metaphysical (or theoretical) statements, divorced from their everyday surroundings, words have no determinate sense whatsoever. Thus, to repeat, he is not concerned to arrive at any new knowledge as such but to inquire into the ways of sensing 'what is possible before all new discoveries and inventions', to inquire into possible new ways of seeing and acting in relation to our present surroundings, ways that can go beyond those into which we have been trained so far.

WOMEN'S POLITICAL EMPOWERMENT

Women's political empowerment is the modern notion of the first struggle for women's suffrage—the right to vote and to run for office—which began in France in the late eighteenth century. Today, women's suffrage is explicitly stated as a right under the Convention on the Elimination of All Forms of Discrimination Against Women, adopted by the United Nations in 1979.

Women's Political Representation

While there are regional variations in women's representation in national parliaments, they occupy only

18 per cent of parliamentary seats around the world. Representation is highest in Nordic countries at 42 per cent and as low as 10 per cent in Arab countries.

There is much truth in Nussbaum's observation that unless nations place the special needs of women as central to development goals, there cannot be overall improvement in addressing issues of poverty and development. For this, women must be represented at the political level, one of the highest levels of decision-making in a country—their voice, needs and concerns articulated at every stage, from conceptualizing to the planning and implementation of programmes that affect their lives. This entry seeks to draw linkages between the processes that empower women leaders within political institutions and the process of action research.

Political representation alone cannot be an adequate measure to ensure women's participation and inclusion in the exercise of their agency. Women political leaders need knowledge, soft and hard skills, relevant information with regard to political processes and political issues and the appropriate use of this learning to influence decisions in ways which enable them to initiate change in the structures of power they belong to, paving the way for others who follow.

Importance of Political Empowerment

Women's political empowerment is envisaged as the vehicle that allows women to exercise their leadership and develop the potential to analyze their specific needs and the challenges that prevent them from realizing the same and negotiating these from a position of authority and strength. Political empowerment also implies enhancing individual competencies, building collectives and developing collaborations and networks for women to be effective agents of change.

According to Martha Farrell and Mandakini Pant, more important than exposure to ways of governance and strategies in the effective administration of their office is the need to draw the attention of these political leaders to analyze the factors that render women's voices invisible, that exclude and marginalize individuals on the basis of their sex and prevent the exercise of their agency.

The process of collective learning is a powerful tool enabling women to understand gendered identities and practices that often act as forces for exclusion of women from leadership positions. Workshops, discussions forums, training programmes and the formation of women's networks and collectives for women's political empowerment are based on principles of adult learning and participation, which perceive learning as

- learner centred, building upon individual knowledge and experience;

- comprehensive, with a focus on awareness, knowledge and skills;
- active and allowing for practical use of the new knowledge;
- centred around real-life issues rather than theoretical concepts; and
- flexible and sensitive to the needs and requirements of the learners.

Women's Political Empowerment and Action Research

A typical adult learning cycle is very similar to the process of action research and comprises (a) the need and desire to learn; (b) sharing the experiences of self and hearing the experiences of others in the context of problem-solving; (c) reflection and analysis of these experiences; (d) building new knowledge and understanding; (e) application of these experiences in their work and practice and (f) changed ways of behaviour and functioning. This process of learning is not a one-time exercise but rather a continuous process of sharing, reflection, analysis, application and action.

Conscientization and critical consciousness, popularized by the Brazilian educator Paulo Freire, are still used as a sociopolitical educational tool for women political leaders. The process of raising awareness of why women are excluded from the mainstream enables them to question the roots of social inequity and initiate processes of political action and social change to remedy their current situations. Women are enabled to analyze that issues related to their exclusion and denial of power to them are very often political ones, because they are based on how women are expected to fit into social and political structures that have been created neither by them nor for them. This process of inquiry enables them to recognize gender discrimination at a personal level, which is rooted in patriarchy, and draw links to its systemic nature.

The increased participation of women in political processes also has an impact on the governance structures, making them gender sensitive and equitable. In India, the constitutional amendments of 1993 mandated that women constitute a critical mass of at least one-third representation at local levels of governance. This brought to the fore the reality of the multiple challenges that women face in their political leadership. It was soon realized that women have no direct exposure to governance; many came straight from the confines of their homes into public office, with few female role models for them to emulate. The process of political empowerment created hundreds of successful women political leaders, whose abilities and competencies created success stories all over the country, as a consequence of which most provincial governments have

increased to 50 per cent the reservation of women in local governance.

The process of women's political empowerment is also closely linked to the development of their leadership, by providing opportunities for systematic learning in order to influence others in the fulfilment of their goals and objectives. The scope for leadership includes placing on the agenda women's issues usually considered 'apolitical', such as health of women and children, education of the girl child, sanitation, potable water, gender-based violence and other issues of safety and security.

Women's political empowerment provides women the insights to use their legitimate political space and the authority to guide processes and influence outcomes that are coherent in their objective of redistribution of power, allocation of resources and creation of opportunities in favour of all marginalized people, especially women.

WORK RESEARCH INSTITUTE, THE

The Work Research Institute (WRI) was founded in 1965 as a part of a group of state-owned research institutes directed at challenges in working life. In 1986, the WRI was separated from the group to continue as an autonomous institution. The ownership functions were later transferred from the Ministry of Labor to three university colleges. Currently, the institute is in the process of being incorporated into the Oslo and Akershus University College.

Since action research was a main activity from the beginning, the institute has half a century of continuous experience within this area. It has had occasion to not only follow but to some extent also spearhead the transformations in action research that have occurred during this period.

From Experiments to Participative Projects

In the beginning, the WRI was strongly influenced by the ideas of Kurt Lewin and, in particular, by the idea of the field experiment. In a major effort, in the 1960s,

to spearhead democracy in work through experiments with autonomous work groups, it was discovered that while experiments could give rise to many processes, in particular various forms of discussions, there was a limited direct impact on working life in general. There was a need for a broad mobilization of the will to change among the workplace actors themselves. Experimental methodologies were replaced by more participative research contributions, pertaining mainly to mobilization of those concerned and organization of the process of change. That the efforts would, in spite of a more modest role for research, still aim at autonomy was thought to follow from psychological needs inherent in all people. However, the unions did not want to rely purely on this kind of force and promoted the incorporation of autonomy and participation in the institutional conditions of work defined by society. In particular, in the period from the middle 1970s to the middle 1980s, the WRI was directly involved in processes of legislation and labour agreements in Norway.

A Communicative Turn

With the growing focus on the distribution of influence over the change processes, there emerged a turn towards the medium in which influence is exerted—workplace conversations. When, in 1982, the labour market parties made an agreement on development, the main focus was on how to initiate and structure labour-management communication. In co-operation with action research, a form called democratic dialogue was developed and the Dialogue Conference became the ideal arena for broad participation in change.

Clusters, Networks and Regions as Units of Change

As early as the 1970s, an effort was made to use inter-enterprise conversations as a lever in change. From the late 1980s, the idea was further expanded towards the establishment of networks and clusters of organizations. For action research, this implied a corresponding continuation of the shift towards inter-organizational processes as a main theme. The WRI came to focus in particular on how to link actors to each other and on how to develop and sustain collective self-understandings that can keep disparate actors with no common steering mechanism working together over long periods of time.

Around the turn of the millennium, the notion of regional development attracted political attention. The government promoted the formation of regional partnerships to take charge of policy within areas like sustainable development and innovation. Clusters and networks of organizations were to be linked

to each other within a regional context and, through this, provide a foundation for prosperous regions. For action research, the regional partnerships became new partners, and action research faced the challenge of translating local and network experience into regional perspectives on policy and development.

Change as Social Movement

A development towards seeing change as a broadly framed social process has continued with the introduction of the notion of 'social movement' to describe the nature of the process. In a social movement, many actors move in the same direction, with exchange of impulses between them as the chief generative mechanism, but in different ways and at different speeds.

Learning Over Time

Action research is often seen as a family of approaches where differences are accounted for in terms of theoretical differences or differences in societal context. The continuous work with more or less the same partners within the same context has made it possible for the WRI to see differences in research perspectives from a longitudinal perspective. The communicative turn that occurred in particular in the 1980s, for instance, did not start with a theoretical rethinking or a shift in context but with a reorientation away from design and towards the generative mechanisms as such emerging out of experience with the previous design strategies.

Along with these changes, there have been changes in the role of the WRI itself. The strong historical link between action research and small-group dynamics has, to an increasing degree, been replaced by an action research that sees itself, and is seen by others, as an actor in the discourses and processes that shape society. Field projects, which by necessity have a modest scale, are no longer performed to create models for replication on a broad front but to charge and recharge concepts used in societal-level discourses—such as democracy, participation, autonomy, trust—with the kind of meaning that can be achieved only when the concepts are used in contexts where they can be linked to observable behaviour.

The move towards work reform initiatives acquiring the shape of broadly framed social movements has implied the involvement of a number of research institutions in co-operation, but to some extent also as bearers of different theories about, and approaches to, organization development. The challenge is how to achieve, in spite of these differences, a strengthening of action research through co-operation within the research establishment itself.

WORK-BASED LEARNING

Work-based learning (WBL) entered the lexicon of higher education in the early 1990s as a term to describe learning that takes place in, for and through work. It is not a work placement, although the participant is usually employed throughout the learning process. It is not *in-service training*, a term more commonly used for courses designed elsewhere and run in the workplace. It is not a traditional form of distance learning, but neither is it campus based. WBL is distinguished most clearly in its curriculum. Its programmes are designed around the learning needs of the practitioners and their workplace rather than the conventional disciplinary frameworks of the educational institution. It is learning embedded in the social, economic, political and cultural context of work. This entry introduces the characteristics and origins of WBL and discusses the common ground it shares with action research in practice-centred inquiry leading to personal, organizational and social transformation.

WBL is a significant development in educational practice that reflects the shift from an industrial to a knowledge-based society. Although not represented on the balance sheet, knowledge has become an essential asset in all sectors of public, private and not-for-profit organizations. Knowledge that generates wealth or impact is contextual, timely and, above all, practical. ‘Knowing how’ complements ‘knowing what’ as a vital ingredient of success. WBL has become an umbrella

term to describe this kind of knowledge acquisition—learning that is focused on achieving specific outcomes of significance to business or organizational objectives.

Origins

In simple terms, work is a productive activity undertaken by an individual or group of people to achieve worthwhile outcomes. It may or may not be remunerated. It can be understood in its widest sense to include the multitude of ways in which people act purposefully in the world. It is interesting to note that we often identify ourselves through our work, and the workplace can teach us a lot about ourselves. Work can be the place where we grow, acquire new skills and develop wisdom.

WBL emerged in the last decade of the twentieth century as a way of defining and developing learning in, for and through work. There were two principal drivers in this development: (1) policy initiatives to widen access to higher education and (2) technological changes that resulted in a significant increase in the demand for knowledge in the workplace. In the new knowledge economy, intellectual capital has become the measure of organizational wealth. The workplace is no longer just a site of economic production but also of knowledge creation.

No longer can business or the public sector rely on skills training alone to equip their workforce. Knowledge has become an essential aspect of work, with the consequence that we are witnessing a shift from training to learning in the workplace. This is more than a semantic difference. Staff development is no longer just about the transfer of skills but also the development of an attitude of inquiry that is open to fresh ideas and innovation. Learning in, for and through work has become an essential part of the productive ecosystem, which must adapt to meet the needs of the people involved in it and the organizations that embrace it. Knowledge has become a dynamic commodity, and new ways of recognizing and enhancing it are needed in the global marketplace. The workforce is also becoming more mobile, and individuals are looking for transferable qualifications.

WBL is also shaping higher education, which is seen as a field of study with its own standards and mode of study, offering an approach to professional development across the university curriculum. As work and learning converge, the institutions of higher learning are adapting to align the requirements for university accreditation with the lifelong learning of individual workers and the long-term development of organizations. Formal learning is no longer seen as a contract between the institution and the student but is located in a partnership between the institution, the employer and the employee.

Several influences in higher education have preceded these developments. Work placements have long been included in teaching, social work, nursing and engineering, although their contribution to formal learning outcomes was limited. University structures were not able to keep up with the expanding range of professional and academic interests of students, and they began to expand Independent Studies from a single course to full degree programmes, giving individuals or groups an opportunity to negotiate learning outcomes specific to their own interest and need. This was further enhanced by systems designed to recognize learning acquired in other institutions or from experience. Individuals were able to negotiate their own learning agreements and obtain recognition based on a portfolio of prior learning. These developments provided the emerging field of WBL with the basic tools needed to recognize learning in, for and through work.

Characteristics of WBL

WBL is a broad and expanding field of learning, leading to qualifications at all levels of higher education, from certificate to doctorate degrees, and in all professions. It has several significant characteristics:

- WBL recognizes that learning is already happening in the workplace. It does not initiate the learning process. Practitioners are continuously reshaping their practice through experience and interaction with others. WBL recognizes that learners bring significant prior knowledge (often tacit) into the formal learning process. Everyone is an emerging expert in his or her own practice.
- WBL engages with the interests and needs of the workplace, not the disciplinary boundaries of the university. However, while the WBL curriculum is project oriented, focusing on the desired outcomes of the participants and their employers, not the learning outcomes of subject-based study, it is set in a framework designed to pose cognitive and experiential uncertainty in order to deepen critical awareness and achieve worthwhile ends.
- WBL is as much about the development of the learner as about what is learned. It is about becoming a good practitioner, about making good choices, about treating others with respect—ultimately about transforming work practices to achieve worthwhile aims while at the same time transforming the practitioner. It therefore addresses questions of personal identity and values.
- While WBL can and does occur on an individual basis, there is a growing

commitment to WBL, which is expressed in partnerships among participants, their employers and institutions of higher learning. This has obvious benefits in providing a context in which the learning can be supported and practised and offering a return to the sponsoring enterprise in aligning personal development and organizational mission.

- The curriculum of WBL is work. Work, in all its variety, does not map easily onto the traditional disciplinary frameworks of college or university study. It is transdisciplinary in nature. As a result, learning is assessed through generic learning outcomes that focus on the quality of inquiry and judgement evident in the learning. Disciplinary knowledge is not, however, excluded. It may be necessary for practitioners to acquire specific knowledge relevant to their field of professional practice, and this may be included in a learning agreement.

Knowledge Creation

Various scholars have recognized what has been called the ‘practice turn’ or the ‘action turn’ in the social sciences. Both recognize that work is often conducted in turbulent conditions, in which knowledge is in constant flux. Yesterday’s knowledge is a poor fit for today’s challenges. In a widely referenced publication, Helga Nowotny and her colleagues drew attention to the way in which the boundaries between the context in which knowledge is produced and the context in which it is used have become blurred. What they call Mode 1 knowledge arises from rigorous inquiry in closed groups using established methods. Once published, Mode 1 knowledge may be applied in practice. Mode 2 knowledge, on the other hand, emerges from socially diverse sources and a wide range of practitioner experience. It is oral, contextual, multilayered and often contested. Mode 2 knowledge has open boundaries. From the perspective of the academy, it is transdisciplinary. It is, as Nowotny suggests, inherently transgressive. Its philosophical roots are in Aristotle, Dewey, Heidegger, Gilbert Ryle and Polanyi, amongst others.

While Mode 1 knowledge may be necessary to meet the baseline requirements of the workplace, Mode 2 knowledge is critical to the practitioners’ attempts to enhance and transform their practice. Knowledge that is located in the intentions, actions, experience and sense making of the participants rather than in empirical data and logical reason is, of course, open to social and political influence—a challenge faced by both the work-based learner and the action researcher.

WBL and Action Research

WBL and action research share common ground. They sit Janus-faced at the interface between academia and what Jürgen Habermas called the lifeworld, engaging on the one side with the discourses of the academy, wrestling for recognition of transdisciplinary or multiple ways of knowing, and on the other side seeking to articulate in coherent ways the complex and messy reality of daily practice. Both borrow widely from the tools of psychology, sociology and political analysis. Both are committed to practical ends. Both straddle the boundary between the personal and the professional. They share a pedagogy that enables learners to reflect on who they are and on the choices they make and not just what they think. Both value the qualities of personal judgement and collaboration. Both reach beyond simplistic notions of reflective practice to engage critically with their context and practice.

WBL and action research share an epistemological position that recognizes that the best way to understand a situation is to participate in it. They are committed to exploring the interactions between individual cognitive experience and collaborative forms of knowing. They both recognize multiple ways of knowing—knowledge can be conceptual, but it may also be experiential, practical, expressive, and intuitive. They both bring together the experiential and the rational in pursuit of a greater wisdom than is possible from an exclusive focus on one or the other. These two perspectives by which the individual interprets reality exist as two different cognitive processes that when aligned provide a richer source of inspiration for deliberative action. The one gives attention to emotional, narrative and affective perception, the other to the verbal and analytical.

Prospects

While sometimes employing disciplinary knowledge or research methods, WBL flows beyond the boundaries of the disciplines in pursuit of a more unified way of knowing. It draws from a wide range of research methods, although action-based approaches are likely to predominate and many practitioner-researchers adopt multiple methods. As a field of inquiry, WBL is reflexive, responding to changes in the economic, social and business environment and leading the way in the transformation of higher education. At the heart of WBL is a commitment to effective partnerships between the academy, the employer and the employee in the creation of productive knowledge. It is well placed to address the wider ecological implications of economic and social action. As a flexible and yet rigorous approach to learning, WBL can play a significant role in the transformation of our economic, social and educational systems.

In many of these respects, action research is a natural partner to WBL, although in the segregated structures of higher education there has been little opportunity for cross-fertilization. Many in the WBL community view action research as a methodology or as a source of practice-based tools of inquiry, perhaps unaware of its holistic systems approach to the complexity of the practice situation. While action research can benefit from the insistence of WBL on practical outcomes (impact), WBL may find it helpful to explore the ontological roots of action research in a participatory world view that leads to open, co-operative forms of inquiry. In their shared pursuit of an epistemology of practice, WBL and action research bring to the knowledge economy the conceptual resources, pedagogy and practical tools needed to recognize, accredit and improve good work.

WORKERS' PARTICIPATION IN OCCUPATIONAL HEALTH AND SAFETY

The origin of occupational health and safety dates back to the time of the Industrial Revolution, when millions of workers employed in factories and industries worked under inhuman conditions. It was a time

when no provisions towards ensuring safety and security with regard to the health of the workers existed. The gap between the employers and the employees (workers) was huge, leaving no scope for the latter to express their grievances. As the society was purely capitalistic, the 'rule of the jungle' prevailed, where one group of people suppressed another group. It was a conflict between the powerful and the powerless.

In contrast to this, participation was an egalitarian concept, attempting to bring the workers at a level equal to that of the employer. The concept of participation began to be understood and embraced in the mid twentieth century and later, when a substantial amount of thought went into devising strategies towards addressing safety and health concerns among workers. There was a realization that in order to address occupational health and safety concerns, the employees' perspective should be taken into consideration. This entailed creating spaces for workers to engage in the institutional systems and creating avenues for them to participate in ensuring better health and safety conditions within the workplace. Efforts were undertaken towards engaging workers in the process of planning, decision-making, implementation and evaluation and monitoring, processes from which they had been initially excluded.

In order to ensure that the workplace became safe and hazard free, the engagement of workers was felt to be necessary. The reason was that the worker was aware of the real challenges existing within the workplace and, based on his or her experience and expertise, would be able to suggest solutions towards addressing those problems. This has been the key premise of the 'participatory approach', which gives importance to the perspective of the common people, the ones at the grass roots, that is, the workers.

Strategies on Workers' Participation

The EU-OSHA (European Agency for Safety and Health at Work) describes workers' participation on health and safety issues as a two-way process, where employers and their worker representatives speak to one another, listen to each other's concerns, share information and views, discuss various issues, take decisions together and share a relationship of trust and respect.

Employers should involve workers in all discussions pertaining to health and safety within the workplace. This would mean the involvement of the employer and the worker in each stage of planning and decision-making regarding health and safety issues. Right from the identification of the problem till the stage of devising strategies and solutions, the involvement of both is necessary. For example, the team designing a proposal or framing a policy on health and safety for the

organization must comprise both employer(s) as well as representatives from amongst the workers. Furthermore, workers should also have a role in monitoring and evaluating a particular plan or a health and safety mechanism within the workplace. Feedback from workers must also be sought, as they constitute a major percentage of the workforce. Such measures loosen the hierarchies, making both employer and employees equally responsible.

Various mechanisms could be adopted to ensure the participation of workers as well as the management:

Safety Committee

Safety committee refers to a group comprising top management, supervisors and worker representatives. The key objective is to ensure that worker representatives provide information to the management on health hazards, accidents and safety-related issues within the workplace. The committee may undertake activities such as inspection, investigation of accidents as well as suggesting recommendations for the future.

Attitude Surveys

The objective behind attitude surveys is to ensure a wide degree of participation by workers. It is to understand how the workers perceive the organization. It seeks workers' opinion on the workplace culture, management-worker relations, career development, working conditions, policies and procedures, safety concerns, overall satisfaction and so on.

Focused Groups

Another name for face-to-face interaction within groups could be termed as *focused groups*. Focused groups can be composed of only workers or a combination of management and workers. The aim is to discuss issues in an informal manner by eliciting people's opinions. Workplaces could have focused group discussions, where workers are specifically asked about their opinion on health and safety provisions within the workplace or if the available safety mechanisms are enough to address the health hazards within the workplace. In industries where both female as well as male workers are employed, focused groups can be organized separately for female workers and then for male workers, to specifically gain insight on the different concerns and priorities of both.

Quality Circle

Another name for Quality Circle is Safety Circle. The purpose is that in addition to involving workers in discussion of occupational health and safety management, Quality Circles involve workers in planning,

decision-making and the management of occupational health and safety.

The true purpose of participation is served when the workers are provided a platform to express and are made to realize that their opinions are equally valued within the workplace. Being the ones exposed to risks, workers are in a position to understand the root cause behind health hazards or accidents occurring within their workplace. Globally, millions of workers employed in factories and industries handle heavy machinery and work under extreme temperatures, most often without proper lighting or ventilation. Thus, workers are the ones exposed to the maximum risks and accidents. Based on this very rationale, participation of workers in ensuring occupational health and safety becomes an essential component.

WORK-FAMILY INTERVENTIONS

Second generation approaches to work-family interventions focus not on policies but on deeper level changes in organizational cultures. The goal is to change the way work is accomplished—its design and its norms and expectations—so that employees are better able to align their employment with their personal lives. It is a way, also, of making the workplace more gender equitable. The method used is called Collaborative Interactive Action Research (CIAR).

Changes in work practices geared to better aligning work and personal life are particularly difficult to accomplish because they are linked to two sets of gendered organizational assumptions: one about the ideal worker and the other about ideal work. Organizational norms about ideal workers are implicitly linked to stereotypical notions of professional masculinity, such as strength, assertiveness and a life situation that includes

someone else taking care of family and other personal issues. Assumptions about ideal work practices are linked to a set of beliefs about the use of time and space, the role of managerial oversight and evaluation measures that are also anchored in traditional notions of masculinity. Less obvious but critically important is the fact that these gendered images also have an unexpectedly negative impact on work effectiveness. CIAR explicitly links equity and effectiveness—two objectives long thought to be adversarial—and promotes a dual agenda. It challenges the deeply embedded assumptions about ideal work and the ideal worker and does so in actionable ways.

Though collaboration is part of most action research, CIAR is somewhat different because it rests on a mode of interaction that is self-consciously based on mutuality and fluid expertise. Mutuality brings two types of expertise together—the researchers' on gender dynamics and the organization's on work practices and systems—to create new, actionable knowledge. The process is explicitly fluid and two directional. This type of collaborative interaction requires the typical skills of action research, but using these presents special problems because these skills are themselves gendered, associated with the feminine, domestic sphere of life. Enacting them can engage strong, even disproportionate resistance. Exploring, rather than attempting to overcome, this resistance provides additional data about the gender dynamics at play and the work practices to examine.

The action part starts at the point of entry into an organizational site. Whether entry takes the form of a survey, interviews or focus groups, its primary goal is to connect—explicitly and from the beginning—the goals of equity for people's work-family concerns with effectiveness issues in business. Therefore, the initial interviews probe the details of work as well as family and try to elicit a new, shared understanding of how these are connected and not necessarily adversarial. The interviewer is not passive in this process but actively engages the interviewee to surface and challenge assumptions. The goal is to bring together the two domains of equity and effectiveness at the level of everyday work practice. These mini-interventions prepare the work group for a larger experimental intervention, which is designed collaboratively. The design must address both sides of the dual agenda and include outcomes to be evaluated.

Finally, the research part is the one aspect that is not collaborative and hence different from other types of action research. In CIAR, the researchers alone analyze the data. It is their expertise. Looking at data to identify taken-for-granted assumptions that unexpectedly have negative consequences for equity and effectiveness requires an understanding of gender dynamics

not usually available in the organization, though it is a goal of the process to introduce this understanding. Feedback is perhaps the key intervention: It provides a new narrative about work practices and opens up the possibility of change.

Take the example of the finance department of a large manufacturing site. One assumption identified there was that 'time is cheap'—in other words, when problems arose, the most common resource deployed was time, ignoring the costs of that practice for both equity and effectiveness. This led to a culture of *overdoing* work. When senior managers requested information, junior analysts would develop a full-blown analysis, complete with graphs, charts and even supporting presentations before going home that night. The problem was that this level of analysis and the immediacy of the response were rarely required. Often a simple back-of-the-envelope analysis was all that was needed. The analysts, however, were reluctant to ask about the technical or time parameters of the task because they did not want to raise questions about their commitment or competence. Instead, they took it as an opportunity to shine; to show the senior managers that they were willing to go the extra mile. These norms had dual agenda consequences. Overdoing led to unnecessary long hours and unpredictability in schedule, which was particularly problematic for personal life. But it also had significant effectiveness implications. Wasting time on unnecessary analysis meant that other tasks were ignored or under-analyzed, leading to productivity and efficiency issues. The team were asked to come up with a simple, actionable step to change this informal norm. They quickly devised a one-page form that asked senior managers to describe the parameters of each request and when the data was needed. The form took the onus off of individuals to ask clarifying questions and encouraged managers to think more seriously about requests and the cost and benefits of what were often casual inquiries. As one senior manager noted, 'I had no idea folks were staying till all hours to get these things done. I usually don't read them until the end of the week'. In retrospect, it seems an obvious solution. But without surfacing the assumption about time, these inefficient practices would not have been identified or been able to be changed.

In summary, CIAR is a mode of action research particularly well suited to work-family interventions. It is geared to identify gendered assumptions that not only hurt equity issues related to personal life but also detract from effectiveness. Importantly, it offers organizations an opportunity to rethink previously unquestioned work practices and develop concrete, work-based changes that are systemic and structural, creating workplaces that are good for people and good for work.

WORLD CAFÉ, THE

The World Café is an interestingly paradoxical process. It is a social technology for engaging people in conversation. It uses a tightly controlled format to generate free-form conversation, engaging stakeholders in meaningful dialogue to identify and shape future directions for action. It is not primarily intended to find answers but to generate a broad range of perspectives for influencing inclusive, ongoing attention to strategies, goals and tasks. It may, therefore, be of less use to individuals conducting research on theoretical topics. As an action research method, it employs short-term (usually ½ to 1 day in length) intentional engagement of larger numbers of individuals exploring tightly focused questions requiring targeted input from different perspectives.

Description

While specific content may vary widely, every World Café applies a single set of design principles with three common features: (1) the visual appearance of the setting for the conversation, (2) the roles enacted by those involved, and (3) the use of carefully chosen questions, graphics and writing to generate and collect data and information. The concept originators list seven underlying design principles on their website:

1. Set the context.
2. Create a hospitable space.
3. Explore questions that matter.
4. Encourage everyone's contribution.
5. Connect diverse perspectives.
6. Listen together for patterns and insights.
7. Share collective discoveries.

The visual appearance is that of a 'café', and whether it is a huge arena with hundreds of participants (as used at the 1995 SoL Global Forum in Vienna) or a small meeting room with as few as 20, the features are common to cafés around the world. There are tables for 4, with colourful tablecloths and interesting centrepieces. The room is informal and well lit, and there is usually no obvious presenter's podium. However, the 'implements' are different from the usual café scene—the tables have an extra 'cloth' of oversize sheets of paper and are strewn with coloured pens; one or more walls may be covered by huge sheets of blank paper; posters on the walls advise participants to

- focus on what matters,
- listen to understand,
- contribute their thinking,
- speak their minds and hearts,
- link and connect ideas,
- listen together for insights and deeper questions,
- write and draw on the 'tablecloths', and
- have fun.

Process

The key roles in a World Café event are the client, the facilitator, a few presenters, 'hosts', participants and a graphic recorder. The client nominates the Café topic, guides the selection of participants, outlines the questions to be addressed and may also participate. The facilitator introduces the process, controls the timing and movement while otherwise not engaging with the emerging content of the event. Presenters, given the task of provoking conversation and dialogue, abide by the client and the facilitator's guidelines to produce short introductions to a series of 'powerful questions' (see below for explanation) to encourage dialogue. The host role is adopted and retained by one person at each table or may be shared among participants as the event proceeds. Participants create conversations—generating ideas and information for collection. The graphic recorder observes and analyzes the event—turning the participants' words into original images that gradually coalesce into a visual representation of the flow of the event.

The first presenter introduces the theme, states their thinking on the issue and poses the first powerful questions for exploration during the opening dialogue cycles. Presenters are limited to 5 minutes and may then join a table for the remainder of the event. The facilitator manages the ensuing process. The first cycle begins with introductions—as in any conversation of strangers—and an agreement on who will host the table. The host remains at the table for the remaining cycles, while the other participants relocate to different tables when directed to do so by the facilitator. This arrangement may vary according to the client's goals. After each relocation, the participants introduce themselves, listen as the host briefly summarizes the conversation that preceded their arrival and then pick up the threads by adding to, amending and building on reported ideas as recorded by their predecessors. Depending on the preset sequence, there may be three or more such cycles of relocation before a conversation of all participants draws together the threads of the dialogue about the presenter's question. Agreement is not sought. The goal is generation and recording of as many ideas, concepts, exploratory suggestions and propositions as possible.

The questions posed by subsequent presenters then lead the conversation deeper into exploration of the event's key theme or issue. Each presenter's questions are followed by the same number of cycles of discussion and relocation. Towards the end of the event, there may be a final summing up of key ideas, insights and suggestions for ongoing action. Summarizing and collating all the data collected during the event is usually the task of those sponsoring and directing the World Café. Participants may anticipate receiving a subsequent report—if this is part of the plan for the event.

The use of powerful questions implements the Nobel Prize winner Arno Pensias's recommendation to 'constantly examine your own assumptions'. As described in *The Art of Powerful Questions*, they are the heart of the World Café process—designed to frame exploratory questions about issues that truly matter, without simultaneously expecting immediate answers. Such questions take time to compose, and the client and the facilitator's preliminary work includes ensuring that they sufficiently challenge assumptions and habits to generate deeper questioning and analysis. They are 'problem-finding' tools leading to 'problem-solving' strategies, intended to avoid premature 'leaping to solutions'. Voigt et al. suggest that powerful questions (a) focus collective attention, (b) connect ideas and (c) create forward movement.

For example, a World Café conducted for an Australian mining industry conference asked the participants three questions: (1) What is the real purpose of our regulatory environment? (2) What assumptions

can we challenge about mine safety training? (3) How does education sustain a safe working environment? The results informed the development of immersive learning strategies varying markedly from traditional approaches.

In short, the World Café engages and challenges participants without expecting quick answers but with a deep belief in the value of exploring together to enhance future prospects.

WORLD CONGRESSES OF ACTION RESEARCH

The World Congresses provide a global forum every 2–3 years for participants to meet across disciplinary boundaries to develop and exchange concepts, ideas, experiences and their reflections on current thinking and practice and to explore possibilities for the further development of practice, networks and collaboration.

History of World Congresses, ALARPM and ALARA

The congresses were founded by Australia-based Ortrun Zuber-Skerritt and Ron Passfield, working in the higher education, managerial and organizational learning field in Brisbane in the 1980s and 1990s. They also co-founded the auspice organization the Action Learning Action Research and Process Management Association (ALARPM), renamed the Action Learning Action Research Association (ALARA) from 2008.

The precursor to the world congresses of action research was the first International Symposium on Action Research, organized by Mary Farquhar and Ortrun Zuber-Skerritt in 1988 at the then Queensland Institute of Technology in Brisbane, Australia. This led in 1990 to the inaugural World Congress of Action Learning, Action Research and Process Management. The ALARPM/ALARA World Congresses are hereafter referred to as the World Congresses.

First World Congress 1990—Griffith University, Brisbane, Australia

- Partner organization: Australian Institute of Training and Development
- Convenor: Ortrun Zuber-Skerritt
- Theme: Action Learning for Improved Performance
- Keynotes: Reg Revans, John Elliott, Sheila Harri-Augstein, Laurie Thomas

Second World Congress 1992—University of Queensland, Brisbane, Australia

- Convenor: Patricia Weeks
- Theme: Transforming Tomorrow Today
- Keynotes: Peter Checkland, Bob Dick and Tim Dalmau, Orlando Fals Borda, Brian Hall, Robin McTaggart, Yolanda Wadsworth

Third World Congress 1994—University of Bath, United Kingdom

- Convenors: Pam Lomax and Jack Whitehead
- Administrator: Moira Laidlaw
- Theme: Accounting for Ourselves
- Keynotes: Pam Lomax and Jack Whitehead, Orlando Fals Borda

Fourth World Congress 1997—Convention Centre, Cartagena, Colombia

- Partner organization: The 8th World Congress of the international Participatory Research Network
- Convenor: Orlando Fals Borda
- Theme: Convergence in Knowledge, Space and Time
- Keynotes: Immanuel Wallerstein, Manfred Max-Neef, Agnes Heller, Marja Liisa Swantz, Rajesh Tandon, Robert Chambers, Robert L. Flood, Robin McTaggart, Ted Jackson, Rodolfo Stavenhagen, Anibal Quijano, Peter Reason, Budd Hall, Anisur Rahman, Eduardo Galeano. Paulo Freire was to be lead keynote but died 2 months before the World Congress.

Fifth World Congress 2000—University of Ballarat, Australia

- Partner organization: The 9th World Congress of the international Participatory Action Research (PAR) Network
- Congress advocate: Stephen Kemmis
- Theme: Reconciliation and Renewal—Through Collaborative Learning, Research and Action
- Keynotes: John Gaventa, Evelyn Scott, Susan Weil, Patricia Maguire, Bob Macadam, Susan Goff, Yvonna Lincoln, Martin von Hildebrand, Vijay Kanhere, Susan Noffke, Robert Flood, Mandawuy Yunupingu, Anisur Rahman, Victoria Marsick, Isaac Prilleltensky, Robert Chambers, Deborah Lange

Sixth World Congress 2003—University of Pretoria, South Africa

- Partner organization: The 10th World Congress of the international Participatory Action Research (PAR) Network and five South African technical and higher educational institutions
- Convenor: Tessie Herbst
- Theme: Learning Partners in Action
- Keynotes: Ortrun Zuber-Skerritt and Thomas Kalliath, Peter Reason, Cheryl de la Rey, Susan Weil and Danny Burns, Ineke Buskens, Richard Bowden, Tim Dalmau

Seventh World Congress 2006—University of Groningen, the Netherlands

- Convenor: Ben Boog
- Theme: Standards and Ethics in Participatory Research
- Keynotes: Ben Valkenburg, Yoland Wadsworth, Judi Marshall, Michiel Schoemaker, Øyvind Pålshaugen, Sandra Schruijer, Naomi Scheman, Julia Preece

Eighth World Congress 2010—Bayview Eden Hotel, Melbourne, Australia

- Partner organizations: Institute for Development Studies, UK; Deakin University
- Convenor: Jacques Boulet
- Theme: Participatory Action Research and Action Learning: Appreciating Our Pasts, Comprehending Our Presents, Prefiguring Our Futures
- Keynotes: Alan Rayner, Budd Hall, Linda Tuhiwai Smith, Yoland Wadsworth

Characteristics of World Congresses

Networking

Networking is a central feature of the World Congresses. Ortrun Zuber-Skerritt's European background and international perspective brought to the World Congresses the fields of Action Learning and process management. Her co-organizer Ron Passfield, a strong local networker and publisher, encouraged diversity and a focus on dissemination of thinking.

World Congresses often arise out of partnerships with a related institution or network—most significantly with the international Participatory Action Research (PAR) Network. Three World Congresses were held in conjunction with those of the older international Participatory Research Network (also called World Congresses: 8th in 1997, 9th in 2000 and 10th in 2003).

An important driver is the common experience by action researchers of isolation in situations where the field may be small and diverse or other methodologies have dominated. As an epistemology of change, action research also endures the paradox of simultaneous popularity and unpopularity as it questions how things are and how they could be otherwise. Networking serves a function of strengthening practitioners' confidence and theory of practice.

Individuals attending have been encouraged to network by different methods adopted at different world congresses. These have included daily-meeting affinity groups, the use of hosts and host groups in advance of the World Congress, the presence of central 'open spaces/marketplaces', the continuous availability of refreshments in 'gathering spaces', extensive bring-and-share tables, poster displays and notice boards as well as the formal meeting of named sub-networks, including the five main 'strands, streams and variants' (see below).

Numerous and durable examples of international collaboration, for co-research, co-writing and publishing, journal board participation, inter-country visitation and teaching (including North-South alliances such as Ecuador, Britain, the Netherlands, Tanzania, Australia and Bangladesh, or China, the USA, Bangladesh, Israel and Norway) have followed networking at World Congresses.

Diverse Contexts and Different Foci

The multiple 'strands, streams and variants' around which World Congresses have structured their programmes have emerged from the social, historic, economic and political contexts in which the characteristics of action research have proved relevant.

The five key substantive topic streams have been education, agriculture/environment and farming, health/

welfare and human services, community development, and business and management. The auspice organizations also indicate a natural history of the key methodological interests of Action Learning, action research, process management and systems thinking, as well as the participatory research tradition represented in adult and community education, urban and community development, immigrant/settlement, indigenous, consumer and other critical and appreciative movements, the developing world and the natural environment. Other streams of interest are feminism, evaluation, organizational development, human resources, user-centred design and the climate emergency.

Creative Modes of Presentation

Reflecting the diversity of stakeholders and the methods needed to give voice to people's knowledge, experience, concerns and visions, the World Congresses have experimented with creative, artistic, aesthetic and alternative presentational methods, often in preference to traditional academic methods. World Congresses have pioneered, for example, an informal 'conversation pit', a 'Café of Possibilities', meeting spaces/market places, a 'Garden of Proposals', photographic displays, a video salon, songwriting, narrative creation, memorabilia, dramatic presentations and collective artworks. A conference dinner has on occasion enabled table groups to form small learning communities, for example, to create and present micro-theatres representing key concepts of the field.

Built-In Evaluation

To encourage small, self-correcting action inquiry, World Congresses have developed methods to 'feel its own pulse', that is, to use action research methods to better understand the nature of the World Congress experience for participants. These methods have included roving reporters, photographic and video narratives, a giant ear listening post, check-ins at the end of sessions, reflections by affinity groups or pods at the end of each day, post-Congress written feedback, a published evaluation journal article and follow-up reflection, report-back and sharing sessions by local networks.

Numbers

Typically, attendances have ranged between a low of several hundred and a high of 1,800 at Cartagena in 1997.

Participants in World Congresses

Those attending are employed or self-employed people working in schools, universities, higher education

providers, technical and further education, government research departments, training and development agencies, health care, human resource management, consulting firms, non-governmental organizations, church organizations or community groups, small- and medium-size businesses or large corporations, finance, defence, police, agriculture, travel, real estate, architecture and engineering. Particular World Congresses have attracted more Aboriginal, indigenous and First Nation researchers, self-help group members, service users, patients, consumers, residents, members of other communities-of-interest and citizen activists. To some extent, the philosophy of co-researching has brought groups and teams of people to the World Congresses, crossing boundaries of class and other distinctions.

Governance and Auspice Organization

World Congresses were initially auspiced by the founding group in Brisbane, Australia, but soon began to be hosted in other countries by local groups and institutions. ALARPM formed as a governance vehicle and continues, as ALARA, to be a core contracting, not-for-profit, non-government, community-based association that is committed to continuity. ALARA is legally incorporated in Canberra, Australia. ALARPM/ALARA expanded beyond organizing the World Congresses to develop an interested membership who meet locally or in state or national network meetings primarily in Australia. It also provides membership (called networking) directories, an online open-access journal to circulate practitioners' accounts in accessible written form and national conferences in Australia in the years between the World Congresses.

To ensure that the Australian basis of ALARPM did not skew the governance of the World Congresses, and assisted by a Participatory Action Research process facilitated by Susan Goff, ALARPM's committee of management became more internationally representative in 2001, with more than 20 members, of whom 17 were from countries other than Australia. An attempt to unite within a self-co-ordinating world network-of-networks with other national groups has been discussed at several World Congresses, without practical results to date.

Management of World Congresses

Various experiments with the continuum between central and local control led eventually to risk management of potential losses by the ALARA Management Committee by use of a legally robust Memorandum of Understanding and a linked World Congress Policy as the basis for negotiating each local agreement to achieve transparency and equity. The ALARA's Global

Vice President, supported by these two documents, establishes the World Congress committee or subcommittee and any networked groups to support the committee's work. Typically, there is a local convenor with the local committee, plus overlapping membership of some kind.

World Congresses and the Development of Action Research in Wider Social, Political and Economic Contexts

The World Congresses' themes and the nature of their sponsoring contexts illuminate their hermeneutic character in the context of the wider, co-creating social, political and economic situations. For example, in 1990, the focus on *performance* reflected the concerns of a worldwide post-recessionary context. In 1992, a focus on *transformation* reflected introducing the community development and health and human services streams, which in turn reflected the desire for social change and improvement in a post-war era of change from the 1970s and turbulence after the late 1980s' economic and technological business crash. In 1997, in South America, the focus on *convergencia* reflected the hitherto isolated 'strands, streams and variants' beginning to learn about one another in a rapidly globalizing world economy.

In 2000, the focus on *reconciliation* in Australia highlighted the historic strengthening of indigenous voices taking place, while in 2003, the focus on *learning* was situated within a post-reconciliation 'new South Africa'. By 2006, in the Netherlands, a focus on *standards*, with stronger representation of both agriculture and the environment, reflected a maturing field in a business world wanting to see grounded evidence of quality assurance and outcomes. And in 2010, back in Australia, a focus on *stock taking* indicated the field's growth and consolidation after the long post-war era,

its taking a strong local-global perspective on international development, merging with the new systems thinking, and joining the action research epistemology with biological and ecological systemic approaches, to address more deeply the growing imbalances of wealth, power and environmental degradation worldwide.

Other International Conferences

Over the decades of the World Congresses, a wide range of local, regional and national action research associations, groups and networks also formed around the world, as well as a growing number of consultancies, academic groups and centres. Only one other of these networks has held regular international conferences. Originally titled the Classroom Action Research Network, with a teaching/learning and education focus, the Collaborative Action Research Network broadened to include other professions and disciplines. This UK-based organization, along with the World Congresses, remains the only current opportunity for action researchers and those using related methodologies to meet internationally to further the work of the field.

Y

YOUTH PARTICIPATORY ACTION RESEARCH

Participatory Action Research (PAR) is a general approach to research that counters researcher control over the process of constructing, sharing and using knowledge in favour of participant empowerment and voice and some form of transformational action. All forms of PAR involve participatory or group conceptualization, information collection and the resultant action. Generally, the target populations for PAR are those who have been politically, economically and culturally marginalized. PAR uses participatory research methodology coupled with critical social and emancipatory pedagogy to introduce people who have experienced marginalization and discriminatory practices to new ways of re-learning and representing their own contemporary and traditional knowledge, so as to move the action/policy agenda in their direction. Thus, PAR usually has a specific change-oriented social justice agenda.

PAR approaches evolved during civil rights and rural and urban independence movements in the USA, Canada and countries dominated by colonial orders in Latin America, Africa, Australia, New Zealand and South Asia. It is rooted in the struggles of marginalized working-class people, minoritized racial/ethnic groups, people with disabilities, LGTBQ (lesbian, gay, transgender, bisexual, queer) groups, girls and women and indigenous populations around the world. PAR combines the deep commitment of researchers to reverse the inequities of power, dominance and control, typical of research on populations, with the desire of people affected by structural inequities to move to the centre using a combination of knowledge and political organizational capacity. PAR also is an effort to place the theories, methods and techniques of science in the hands of those who have been excluded in order to raise issues, speak the truth to power and advocate

for change. Changes may be focused on revising policies, building new institutions and improving service delivery, or reversing the structures of power, influence and economics that impede freedom of decision-making, political advancement and social action. The process of advocating for transformative changes frequently brings about significant changes in the PAR researchers themselves. PAR is thus a transformational process working both simultaneously and sequentially, at the community or societal level, within PAR groups engaged in collective action and in the individual PAR actors themselves. The entry provides a general description of Youth Participatory Action Research (youth-PAR or YPAR), followed by a discussion of the theoretical frameworks that inform this approach and examples of approaches and methods for carrying out YPAR projects.

Youth Participatory Action Research

Youth-PAR, defined as PAR with and by young people, is based on a political philosophy and research methodology similar to that of adult PAR, but it takes into consideration child and adolescent development. Youth-PAR is intended to enhance young people's ability to make informed judgements about the social and environmental injustices that affect them and their communities and to take action to address them. The topics they select may relate to negative peer, family and contextual influences; ineffective school or other institutional policies or social service system failures. Ethical considerations require assurance that the research that youth undertake does not place them in positions of undue risk as individuals, within their families or in their schools and communities; that the research and related actions result in some intended benefit and that the experience is not disempowering.

Youth-PAR can be applied to a wide range of different topics of concern to youth. Issues that youth bring up repeatedly in Canada and the USA are sexuality,

pregnancy and sexual risk, stress and suicidal thoughts, violence, racial/ethnic and other forms of discrimination, substance abuse, bullying and homelessness. Young people also express interest in unjust school policies ranging from tracking to inappropriate suspension, conflicting policies regarding work, school and day care for young mothers, racism, language and other forms of discrimination, income inequity, unwelcoming environments, gaps in adequate food supply and inadequate service delivery. Internationally, youth have conducted PAR for HIV prevention in Brazil, Africa and Bosnia and Herzegovina, human rights and responses to civil strife and war in Sri Lanka, project and service development in England and the use of pesticides in El Salvador.

Theories Used in Youth-PAR

The goals of youth-PAR focus on empowerment and transformative change at the individual, group, community and structural levels. Theories guiding youth-PAR as a programmatic or intervention approach must be relevant to all of these levels and guide reflection instruction or action. They include critical, ecological, identity, sociocultural, empowerment and co-constructive instructional theories.

Critical theories focus analysis on the structural barriers to achieving greater equity. Critical educational theorists, who provide the conceptual underpinnings of youth-PAR, work from the premise that formal and informal educational institutions have a responsibility to address issues of inequity through the engagement of students and instructors in analysis and interpretation of the structures of power, dominance and oppression. One purpose of such analysis is to improve life chances for students who are marginalized. Paulo Freire and Orlando Fals Borda articulate the right of people living in oppressed circumstances to conduct a group analysis of the structural and experiential contradictions in their lived experience, which would lead them to radical change. Each of these frames of reference emphasizes the oppressive nature of traditional power structures and demonstrates the important role of 'hope', a concept that connects structural analysis to action and empowerment. 'Hopeful' resistance to structural limitations and barriers occurs through examining, reflecting and acting to change institutions that constrain more equitable distribution of resources (economic, educational, etc.) across communities or groups.

Ecological theories as articulated by the work of researchers like Urie Bronfenbrenner and Joy Dryfoos situate individuals in a social system, thus providing an analytic framework that enables identification of sources of power and oppression, risks and resources.

Bronfenbrenner's model points to the interaction among system components, thus calling for a systemic or multilevel, community-wide approach to research and intervention. A risk-protection framework, first proposed by J. David Hawkins, Richard Catalano and Janet Miller, offers a means of identifying risk and protective factors at multiple levels. Youth-PAR takes advantage of both, using critical ecological theory to identify and locate power differentials and individual and group social and health risks and stressors and supports in various sectors (family, peer, school, work, community, etc.), examining the effect of these on behaviour within the system.

A variety of theories about ethnic heritage, cultural bonding and identification with the 'cultures or countries of origin' permeate the literature on identity, and we believe that these theories are important in reinforcing the pride and power of racial/ethnic and ethnic/cultural groups that have been marginalized. Pride in community, culture or country of origin is an important protective factor, enabling youth to withstand multiple forms of criticism and stigmatization. At the same time, many young people are more concerned with sharing major elements of a common, globalized 'youth culture' consisting of music, clothing and fashion, role models, values, experience and beliefs about the future. In local settings, youth often self-define into groups that share common interests and goals (skateboarders, Goths, gang members, etc.). Youth-PAR programmes must pay attention to commonalities and differences in the ways in which youth define themselves, affiliate with one another and differentiate between themselves and 'others'. This is important in terms of both forging PAR group identity and understanding the communities and other settings in which youth-PAR efforts try to bring about change.

Recognizing and addressing power differentials at multiple ecological levels and interpersonally through positionality and reflection (e.g. recognition and negotiation of one's status in relationship to power) are critical to youth-PAR, promoting and protecting equitable sharing of power, knowledge and action. Youth-PAR recognizes the fluidity and transitional status of identities that shift with developmental stage, setting, choice and constraints. Among youth in diverse environments, ethnic heritage, peer relationships and social groupings, and global youth culture intersect in unpredictable ways in local settings. Thus, identity considerations must be embedded in any youth-PAR approach.

If power refers to the capacity of the 'unit' (individual, group, community) to exert agency to 'solve its own problems', empowerment can be defined as processes that enhance the capacity to do so through voice, individual or collective action and social justice.

Critical ecologists link individual empowerment supported in a group setting to transformational processes in group and community settings, which form the basis for youth-PAR for social justice.

Approaches and Methods Used in Youth-PAR

To bring about transformational change, youth-PAR approaches utilize some form of knowledge co-construction for action, including civic engagement, community organizing to address injustices, youth participation in evaluating responsive public services and programmes for young people, and youth knowledge production for social justice. Different approaches balance research/inquiry, reflection and action differently.

Proponents of youth-PAR for civic engagement argue that youth as assets are missing from the social dialogue in their schools and communities and should be included to ensure their future civic involvement. The emphasis in civic engagement is greater involvement of youth as competent citizens in civic institutions and public representation. The PAR approach draws on their assets and offers them the opportunity to shape and hone their own views and become involved in larger social issues. Service learning and environmental advocacy have been important in forms of youth-PAR oriented towards civic engagement, serving mainly mainstream youth and students. An important subset of PAR researchers working with marginalized youth take a critical approach to service learning and civic engagement, arguing that PAR with those marginalized from the civic mainstream (voice, voting, civic service) can enable young people to understand the nature of exclusion and take politicized action to address it.

Youth involvement in community organizing is a growing movement in which young people learn organizing and advocacy skills to mobilize their peers and others to take some form of social action. Adults and/or youth choose the topic, but the favoured form of choice is youth preference. The field of youth organizing, as a whole, is focused on community issues including the following (from the most prevalent to the least): education, racial and ethnic disparities, health, environmental justice, juvenile justice, immigrant rights and issues related to gender and young women. Youth involvement in community organizing focuses on addressing injustices in these areas. It is an effort to involve youth in the formation of active national and international alliances to reduce social, economic and other injustices. Key elements in community organizing are relationship development, 'popular education' (or the non-institutionally based exploration of local knowledge and historical and political injustices) and social action. While the emphasis in community organizing

is on mobilization for action, some research, generally consisting of surveys, mapping and interviews, is conducted to better justify the arguments underlying the organizing effort, and at the same time to strengthen the voices of youth.

Youth involvement in research and evaluation (YRE) is a third approach to youth-PAR and focuses on evaluation as research. It attributes empowerment to youth involvement in the evaluation of social, educational, recreational and health/mental health services and policies that are important to them. Typical youth-PAR methodology is used to involve youth in identifying service delivery problems, using research methods to address the scope and effect of the problems and using the results to suggest changes. Proponents of YRE, like Kim Sabo, argue that youth affected by poor-quality services will have a larger impact on improving them than adults. YRE may or may not achieve critical analysis or transformational change.

Youth-PAR as knowledge production for social justice is the least well known and the most comprehensive of the approaches. It balances collective knowledge production with action outcomes. It uses eco-critical and self-reflective approaches to enable youth to focus on the root/structural and social causes of a problem. The process of knowledge construction is based on lived experience, group reflection, examination of injustices in the environment and reaching consensus on a common issue to be investigated and changed. These elements are typical of most youth-PAR approaches. Knowledge production for social justice, however, as developed by the Institute for Community Research in Hartford, goes beyond this to introduce interactive, face-to-face empirical ethnographic research methods that enable young people to test their own experiences and ideas with those of others, both adults and peers, while enhancing their logical thinking, social and communications skills. Youth learn multiple research methods, create a hypothetical research model identifying the perceived structural, social and individual causes of their identified problem, develop tools and collect data, analyze the results, present them and develop transformational actions, which in turn leads to more inquiry. In one such example, youth decided to focus on the structural, family and individual factors that promoted the generation of informal or semi-legal forms of income, sometimes referred to as 'hustling', which included pirated CDs and videos, borrowed or illegally acquired clothing and various forms of illegal drugs. After developing a conceptual model within the family, peer and financial domains, they used mapping and a brief survey, which they administered to teens at bus stops, fast-food locations and other sites in the city where small groups of teens gathered, to identify the places where various

items were hustled; pile sorting to understand what teens and adults thought about why teens hustle, what items were more or less risky to hustle and what family situations affect hustling and a longer survey to explore the family, income and peer factors contributing to hustling. After analyzing the data, they came to the conclusion that more and better paying employment programmes for teens would encourage avoidance of hustling. Over the next year, they advocated for youth employment funding at the city and state government levels, spoke to local merchants about job creation and created a job bank at their school. This form of youth-PAR can be conducted with students in school or out of school in summer institutes or camps and after-school programmes. Research methods are linked to academic skills (reading, writing, communication, math, history, science and political science). Reflection is ongoing. By building on youth experience, the approach is culturally, developmentally and contextually appropriate; supports civic attachment and community affiliation and offers opportunities for career exploration.

The Importance of Qualified Adult Leadership in the Conduct of Youth-PAR

Effective youth involvement in PAR depends on skilled facilitators who want to work with youth; can transform research methods into tools for interactive learning and data collection appropriate for elementary and high school children and youth and view themselves as agents of transformative change. At each step in the conduct of youth-PAR, adult facilitators must assess the skills and abilities of youth participants and integrate their lived experiences into their work. Young people in marginalized environments in the USA and elsewhere encounter issues of stigma, discrimination, exclusion, continued exposure to negative feedback and lack of recognition of strengths, assets and accomplishments. Youth-PAR facilitators thus need pedagogical, theoretical and methodological training that highlights the importance of positionality; addresses differences in positionality in instruction and research practice and develops skills in research, reflection and action. Only with personal reflection can facilitators introduce these ideas to young people. In addition to methodological skills and ability to relate to young people, facilitators must be able to model the desired learning behaviours, enable youth to extend their knowledge through interaction with one another and the facilitator and lead students to reflect on their learning and group experience. Thus, selecting and supporting facilitators with appropriate training, motivation, skills and dedication are critical to the approach.

Youth-PAR consists of a set of approaches, methods and tools tested over time that can be applied to any

topic of concern to a group of young people. The field of youth-PAR is well established in the Global North, in particular in the USA, Canada and Australia, but with some exceptions, it has not yet emerged as a major approach to empowering voiceless youth in the Global South. A systematic, theory-driven approach to building leadership and voice among disenfranchised youth, it should be widely supported in schools and communities in countries around the globe. Formal programmes that provide effective training for qualified youth-PAR facilitators are a priority both nationally and internationally to ensure effective programmes of research and action and to help them grow.
